$\mathcal{J}^* = \mathcal{D}^*$ NEED NOT HOLD IN FINITE SEMIGROUPS

ANDREAS DISTLER, VICTOR MALTCEV, AND ABDULLAHI UMAR

Abstract. We provide an example of minimum size of a finite semigroup with $\mathcal{J}^* \neq \mathcal{D}^*$. We introduce the notion of starred stability and prove that every starred stable semigroup has $\mathcal{J}^* = \mathcal{D}^*$.

1. Introduction and Preliminaries

Green's relations are one of the most fundamental instruments in Semigroup Theory. In the hope to expand on the amount of such instruments, in [6] it was proposed to study the *starred Green's relations*, which we now define. So, let S be a semigroup and $a, b \in S$. We say that

- $a\mathcal{R}^*b$ if for all $x, y \in S^1$, $xa = ya$ if and only if $xb = yb$;
- $a\mathcal{L}^*b$ if for all $x, y \in S^1$, $ax = ay$ if and only if $bx = by$.

One checks that $\mathcal{R}^*$ and $\mathcal{L}^*$ are equivalence relations on S. It is a nice fact (which is quite easy to verify) that, for $a, b \in S$, $a\mathcal{R}^*b$ if and only if a and b are $\mathcal{R}$-related in some semigroup containing S; and, dually, $a\mathcal{L}^*b$ if and only if a and b are $\mathcal{L}$-related in some semigroup containing S. Another nice fact is that $\mathcal{R}^* = \mathcal{R}$ and $\mathcal{L}^* = \mathcal{L}$ in any regular semigroup. Also, one sees that $\mathcal{R} \subseteq \mathcal{R}^*$ and $\mathcal{L} \subseteq \mathcal{L}^*$.

By analogy with how $\mathcal{D}$ is defined, now we let $\mathcal{D}^*$ be the equivalence relation on S generated by $\mathcal{R}^*$ and $\mathcal{L}^*$. Note that unlike the case with the classical Green's relations where $\mathcal{R} \circ \mathcal{L} = \mathcal{L} \circ \mathcal{R}$, for the starred case in general $\mathcal{R}^* \circ \mathcal{L}^* \neq \mathcal{L}^* \circ \mathcal{R}^*$, see [3] for an example. However, one readily sees that $\mathcal{D} \subseteq \mathcal{D}^*$.

Now let us discuss how one defines $\mathcal{J}^*$. One first defines the principal star-ideal $J^*(a)$ generated by $a \in S$, and then says that $a\mathcal{J}^*b$ if and only if $b \in J^*(a)$ and $a \in J^*(b)$. The characterisation of star-principal ideals can be taken from [3]:

Lemma 1.1. *For $a, b \in S$, $b \in J^*(a)$ if and only if there exist $c_0, c_1 \ldots, c_n \in S$ and $x_1, \ldots, x_n, y_1, \ldots, y_n \in S^1$ such that $a = c_0$, $b = c_n$ and $c_i \mathcal{D}^* x_i c_{i-1} y_i$ for $1 \leq i \leq n$.*

It is clear that $\mathcal{J} \subseteq \mathcal{J}^*$ and $\mathcal{D}^* \subseteq \mathcal{J}^*$.

It is well-known that $\mathcal{J} = \mathcal{D}$ in every finite semigroup. The aim of this note is to resolve the same question, posed first by Peter Higgins, for the starred case – whether $\mathcal{J}^* = \mathcal{D}^*$ for finite semigroups? We tried to answer this question just by 'bare hand', and could not succeed. Only using GAP [4], we could come up with an example of a finite semigroup with $\mathcal{J}^* \neq \mathcal{D}^*$. We discovered this example by analysing the semigroups in the data library Smallsemi [2]. An exhaustive search in the library revealed that 8 is the smallest size of a semigroup with $\mathcal{J}^* \neq \mathcal{D}^*$ and provided us with a complete list, up to isomorphism or anti-isomorphism, of all 60 such semigroups of size 8. See more details on the search and its results in Section 2.

Key words and phrases. Starred Green's relations, finite semigroups, stability.

The natural next question to ask is under what conditions $\mathcal{J}^* = \mathcal{D}^*$ holds. This holds for finite regular semigroups, for which $\mathcal{R}^* = \mathcal{R}$ and $\mathcal{L}^* = \mathcal{L}$. In [3] it is mentioned to hold for superabundant semigroups. In Section 3 we introduce the notion of *starred stable* semigroups and prove that $\mathcal{J}^* = \mathcal{D}^*$ for such semigroups.

2. Minimal Examples

Consider the following multiplication table:

	1	2	3	4	5	6	7	8
1	1	1	1	1	1	1	1	1
2	1	1	1	1	1	1	1	1
3	1	1	1	1	1	1	1	1
4	1	1	1	1	1	1	1	1
5	1	1	1	1	1	1	1	2
6	1	1	1	2	1	1	2	1
7	1	1	2	1	2	1	1	6
8	1	1	1	3	1	2	5	1

One checks that this table gives rise to a semigroup S. It is easy to see that S is nilpotent (3-generated of nilpotency degree 4 and with 1 being the zero) and consequently all $\mathcal{D}$-classes are singletons.

The relation $\mathcal{R}^*$ in S follows directly from the columns of the multiplication table and respectively $\mathcal{L}^*$ from the rows:

- $\mathcal{R}^*$-classes are $\{1\}$, $\{2\}$, $\{3,5\}$, $\{4,7\}$, $\{6\}$, $\{8\}$;
- $\mathcal{L}^*$-classes are $\{1\}$, $\{2,3,4\}$, $\{5\}$, $\{6\}$, $\{7\}$, $\{8\}$.

We conclude further:

- $\mathcal{D}^*$-classes are $\{1\}$, $\{2,3,4,5,7\}$, $\{6\}$, $\{8\}$.

As mentioned above, $\mathcal{D}^* \subseteq \mathcal{J}^*$. Note also that $2 = 6 \cdot 4$, and so $2 \in J^*(6)$; and that $6 = 7 \cdot 8$ and so $6 \in J^*(7) = J^*(2)$. Thus $2 \mathcal{J}^* 6$ and hence $\mathcal{J}^* \neq \mathcal{D}^*$. One finds:

- $\mathcal{J}^*$-classes are $\{1\}$, $\{2,3,4,5,6,7\}$, $\{8\}$.

Using the data library Smallsemi [2] of semigroups with up to 8 elements in GAP [4] we verified that S has minimal size for a semigroup with $\mathcal{J}^* \neq \mathcal{D}^*$. Our implementation to compute starred Green's relations follows directly their definitions and will be available in a forthcoming release of Smallsemi. We further identified all semigroups of size 8 with $\mathcal{J}^* \neq \mathcal{D}^*$ up to isomorphism or anti-isomorphism. Every semigroup in Smallsemi is uniquely determined by a pair of positive integers: the first component equals the size of the semigroup and the second component is its position within the semigroups of the same size in the library. The following is a list of the second components of the 60 semigroups of size 8 with $\mathcal{J}^* \neq \mathcal{D}^*$:

```

10482808
```

The semigroup S corresponds to the first number in the list and there are further 11 nilpotent semigroups all 3-generated and with nilpotency degree 4. The semigroups have between 1 and 5 idempotents and remarkably in all except one semigroup the idempotents form a subsemigroup. The exceptional case has the identifier $(8, 9294889)$ and its multiplication table is

	1	2	3	4	5	6	7	8
1	1	1	1	1	1	1	1	1
2	1	1	1	1	1	2	2	2
3	1	1	1	1	1	2	2	2
4	1	2	3	4	4	2	3	4
5	1	2	3	4	4	2	3	4
6	1	1	1	1	1	6	6	6
7	1	1	1	1	1	6	6	6
8	1	2	3	4	5	6	7	8

We can now easily create infinite families of semigroups for which $\mathcal{J}^* \neq \mathcal{D}^*$ since this property is preserved by adjoining a zero or an identity to a given semigroup. In this way we obtain examples of every finite size greater or equal to 8.

3. Starred Stability

Recall the following definition, which we take from [5]:

Definition 3.1. A $\mathcal{J}$-class J of a semigroup S is said to be *right stable* if it satisfies one (and hence all) of the following equivalent conditions:

(1) The set of all $\mathcal{R}$-classes in J has a minimal element.
(2) There exists $q \in J$ satisfying the following property: $q\mathcal{J}qx$ if and only if $q\mathcal{R}qx$ for all $x \in S$.
(3) Every $q \in J$ satisfies the property stated in (2).
(4) Every $\mathcal{R}$-class in J is minimal in the set of $\mathcal{R}$-classes in J.

We say that the whole semigroup is *right stable* if every $\mathcal{J}$-class of S is right stable. The notion of left stability is defined dually. A $\mathcal{J}$-class or a semigroup are said to be *(two-sided) stable* if they are both left and right stable.

It is well-known that stable semigroups satisfy $\mathcal{J} = \mathcal{D}$ (see [5]). We would like to prove some starred analogue of this fact. Since there is really no convenient way to put an order on $\mathcal{R}^*$- and $\mathcal{L}^*$-classes, we go for the following definition:

Definition 3.2. A semigroup S is *right starred stable* if for every $q, x \in S$, $q\mathcal{J}^*qx$ if and only if $q\mathcal{R}^*qx$. Dually, S is *left starred stable* if for every $q, x \in S$, $q\mathcal{J}^*xq$ if and only if $q\mathcal{L}^*xq$. Finally, S is *starred stable* if it is both left and right starred stable.

Any null semigroup is starred stable, so the previous definition is not vacuous. Therefore the following theorem gives us a source of (finite or infinite) semigroups with $\mathcal{J}^* = \mathcal{D}^*$:

Theorem 3.3. *Let S be a starred stable semigroup. Then $\mathcal{J}^* = \mathcal{D}^*$ in S.*

Proof. Since $\mathcal{D}^* \subseteq \mathcal{J}^*$, it suffices to show only $\mathcal{J}^* \subseteq \mathcal{D}^*$. So, let $a, b \in S$ be such that $a\mathcal{J}^*b$. By Lemma 1.1 this means that there exist

- $c_1, \ldots, c_n, d_1, \ldots, d_m \in S$ and

- $x_1, \ldots, x_{n+1}, y_1, \ldots, y_{n+1}, z_1, \ldots, z_{m+1}, t_1, \ldots, t_{m+1} \in S^1$ with

$$\begin{aligned} (c_1, x_1 a y_1) &\in \mathcal{D}^* & (d_1, z_1 b t_1) &\in \mathcal{D}^* \\ (c_2, x_2 c_1 y_2) &\in \mathcal{D}^* & (d_2, z_2 d_1 t_2) &\in \mathcal{D}^* \\ &\vdots & &\vdots \\ (c_n, x_n c_{n-1} y_n) &\in \mathcal{D}^* & (d_m, z_m d_{m-1} t_m) &\in \mathcal{D}^* \\ (b, x_{n+1} c_n y_{n+1}) &\in \mathcal{D}^* & (a, z_{m+1} d_m t_{m+1}) &\in \mathcal{D}^*. \end{aligned}$$

From these conditions and Lemma 1.1, we see that $b \in J^*(x_1 a)$. But also $a \in J^*(b)$ and so $x_1 a \in J^*(b)$. Hence $x_1 a \mathcal{J}^* b$. Since $b \mathcal{J}^* a$, we have then that $x_1 a \mathcal{J}^* a$. By starred stability we derive that $x_1 a \mathcal{L}^* a$. Since $\mathcal{L}^*$ is a right congruence, we obtain that $x_1 a y_1 \mathcal{L}^* a y_1$ and therefore $(c_1, a y_1) \in \mathcal{D}^*$.

Now, we notice that $a y_1 \in J^*(a)$ and $b \in J^*(a y_1)$, and so $a y_1 \mathcal{J}^* a$. By starred stability this yields $a y_1 \mathcal{R}^* a$. Thus $c_1 \mathcal{D}^* a$.

In effect, what we have just proved is that without loss of generality we may assume that $x_1 = y_1 = 1$. By the same token we can show that without loss one may assume that $x_1 = \cdots = x_n = y_1 = \cdots = y_n = 1$ and $z_1 = \cdots = z_m = t_1 = \cdots = t_m = 1$. Now our previous conditions imply that

$$\begin{aligned} (c_n, a) &\in \mathcal{D}^* & (d_m, b) &\in \mathcal{D}^* \\ (b, x_{n+1} c_n y_{n+1}) &\in \mathcal{D}^* & (a, z_{m+1} d_m t_{m+1}) &\in \mathcal{D}^*. \end{aligned}$$

From these conditions one derives that $b \in J^*(x_{n+1} c_n)$. But $c_n \mathcal{D}^* a$ and so $c_n \in J^*(a) = J^*(b)$, yielding $x_{n+1} c_n \in J^*(b)$. Therefore $x_{n+1} c_n \mathcal{J}^* b$. But $b \mathcal{J}^* x_{n+1} c_n y_{n+1}$ and so $x_{n+1} c_n \mathcal{J}^* x_{n+1} c_n \cdot y_{n+1}$. By starred stability we derive that $x_{n+1} c_n \mathcal{R}^* x_{n+1} c_n y_{n+1}$ and so $b \mathcal{D}^* x_{n+1} c_n$. Furthermore, $c_n \mathcal{J}^* a \mathcal{J}^* b \mathcal{J}^* x_{n+1} c_n$, and so by starred stability $c_n \mathcal{L}^* x_{n+1} c_n$. In particular, $x_{n+1} c_n \mathcal{D}^* c_n \mathcal{D}^* a$. Together with $b \mathcal{D}^* x_{n+1} c_n$, the latter gives us $a \mathcal{D}^* b$, as required. □

Theorem 3.3 implies that the example from Section 2 is not starred stable.

We also checked with GAP that the converse of Theorem 3.3 does not hold and found that the smallest size of a non-starred stable semigroup with $\mathcal{J}^* = \mathcal{D}^*$ is 4, and that actually there is only one such semigroup of size 4:

	1	2	3	4
1	1	1	1	1
2	1	1	1	1
3	1	1	1	1
4	1	1	2	2

Lemma 3.4. *Let S be a nilpotent semigroup of nilpotency degree 3. Then $\mathcal{J}^* = \mathcal{D}^*$ in S.*

Proof. The zero element of S is a singleton class in both $\mathcal{D}^*$ and $\mathcal{J}^*$. All elements in $S^2 \setminus S^3$ are $\mathcal{D}^*$ related. Let $a, b \in S \setminus S^3$ be two elements that are not $\mathcal{D}^*$-related. Without loss of generality we may assume that $a \in S \setminus S^2$, but by Lemma 1.1 the only elements from $S \setminus S^2$ that can be contained in $J^*(b)$ are those already $\mathcal{D}^*$-related to b. Hence a and b are not $\mathcal{J}^*$-related, completing the proof. □
