

FILIFORM $\mathbb{Z}_2 \times \mathbb{Z}_2$ -COLOR LIE SUPERALGEBRAS

R.M. NAVARRO

ABSTRACT. We continue the study of the filiform $\mathbb{Z}_2 \times \mathbb{Z}_2$ -color Lie superalgebras. All of them can be obtained by using infinitesimal deformations, i.e. cocycles. In this work we give the total dimension of such cocycles (for any dimensions n , m , p and t of the $\mathbb{Z}_2 \times \mathbb{Z}_2$ -color Lie superalgebras). Also, we give a basis of such cocycles in some generic and concrete cases.

2000 MSC: 17B30; 17B70; 17B75; 17B56

Key-Words: color Lie superalgebras, $\mathbb{Z}_2 \times \mathbb{Z}_2$ -grading, cohomology, deformation, nilpotent, filiform.

1. INTRODUCTION

In the understanding of the properties of physical systems is central the concept of symmetry and its associated algebraic structures. In particular, that a better comprehension of the laws of physics may be achieved by an identification of the possible mathematical structures as well as their classification. Thus, for instance, the properties of elementary particles and their interactions are very well understood within Lie algebras. Furthermore, the discovery of supersymmetry gave rise to the concept of Lie superalgebras which becomes central in theoretical physics and mathematics. Color Lie superalgebras can be considered as one of the possible generalizations of Lie superalgebras with physic applications ([3], [15], [16] and [12]).

In this work, we shall consider color Lie superalgebras with a $\mathbb{Z}_2 \times \mathbb{Z}_2$ -grading vector space due to the great amount of physical applications of this vector space, see e.g. [4], [5], [6] and [7]. In particular, we will focus our study in a very important type of nilpotent $\mathbb{Z}_2 \times \mathbb{Z}_2$ -color Lie superalgebra, i.e. filiform $\mathbb{Z}_2 \times \mathbb{Z}_2$ -color Lie superalgebras.

Filiform Lie algebras was firstly introduced in [17] by Vergne. This type of nilpotent Lie algebra has important properties; in particular, every filiform Lie algebra can be obtained by a deformation of the model filiform algebra L_n . In the same way as filiform Lie algebras, all filiform Lie superalgebras can be obtained by infinitesimal deformations of the model Lie superalgebra $L^{n,m}$ [1], [8], [10] and [11]. In [12] we generalized this concept obtaining *filiform (G, β) -color Lie superalgebras* and the model *filiform (G, β) -color Lie superalgebra* as well as the existence of “adapted” basis for these color Lie superalgebras. We too proved that in order to obtain all the class of filiform (G, β) -color Lie superalgebras it is only necessary to determine some infinitesimal deformations of the model filiform (G, β) -color Lie superalgebra.

In [13] we have studied these infinitesimal deformations, i.e. cocycles, for the group $G = \mathbb{Z}_2 \times \mathbb{Z}_2$ obtaining in particular a decomposition into 10 subspaces

that depend on the election of the commutation factor β . In the present work we continue the study of the filiform $\mathbb{Z}_2 \times \mathbb{Z}_2$ -color Lie superalgebras. In particular, we give the total dimension of such cocycles (for any dimensions n , m , p and t of the $\mathbb{Z}_2 \times \mathbb{Z}_2$ -color Lie superalgebras). Also, we give a basis of such cocycles in some generic and concrete cases.

2. PRELIMINARIES

It is considered the abelian group $G = \mathbb{Z}_2 \times \mathbb{Z}_2$, i.e. $G = \{e, a, b, c\}$ with identity element e and $a + a = b + b = c + c = e$, $a + b = c$, $a + c = b$, $b + c = a$.

The vector space V is said to be $\mathbb{Z}_2 \times \mathbb{Z}_2$ -graded if it admits a decomposition in direct sum, $V = V_e \oplus V_a \oplus V_b \oplus V_c$. An element X of V is called homogeneous of degree γ ($\deg(X) = d(X) = \gamma$), $\gamma \in \mathbb{Z}_2 \times \mathbb{Z}_2$, if it is an element of V_γ . Let $V = V_e \oplus V_a \oplus V_b \oplus V_c$ and $W = W_e \oplus W_a \oplus W_b \oplus W_c$ be two $\mathbb{Z}_2 \times \mathbb{Z}_2$ -graded vector spaces. A linear mapping $f : V \rightarrow W$ is said to be homogeneous of degree γ ($\deg(f) = d(f) = \gamma$), $\gamma \in \mathbb{Z}_2 \times \mathbb{Z}_2$, if $f(V_\alpha) \subset W_{\alpha+\gamma}$ for all $\alpha \in \mathbb{Z}_2 \times \mathbb{Z}_2$. The mapping f is called a homomorphism of the $\mathbb{Z}_2 \times \mathbb{Z}_2$ -graded vector space V into the $\mathbb{Z}_2 \times \mathbb{Z}_2$ -graded vector space W if f is homogeneous of degree e . Now it is evident how we define an isomorphism or an automorphism of $\mathbb{Z}_2 \times \mathbb{Z}_2$ -graded vector spaces.

A superalgebra $\mathfrak{g}$ is, in particular, a $\mathbb{Z}_2$ -graded algebra $\mathfrak{g} = \mathfrak{g}_0 \oplus \mathfrak{g}_1$. Then if we denote by $[\cdot, \cdot]$ the bracket product of $\mathfrak{g}$, we have $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] \subset \mathfrak{g}_{\alpha+\beta \pmod{2}}$ for all $\alpha, \beta \in \mathbb{Z}_2$. Thus, we call $\mathfrak{g} = \mathfrak{g}_0 \oplus \mathfrak{g}_1$ a **Lie superalgebra** if the bracket product satisfies the following identities:

1. $[X, Y] = -(-1)^{\alpha \cdot \beta} [Y, X] \quad \forall X \in \mathfrak{g}_\alpha, \forall Y \in \mathfrak{g}_\beta$.
2. $(-1)^{\gamma \cdot \alpha} [X, [Y, Z]] + (-1)^{\alpha \cdot \beta} [Y, [Z, X]] + (-1)^{\beta \cdot \gamma} [Z, [X, Y]] = 0$
for all $X \in \mathfrak{g}_\alpha, Y \in \mathfrak{g}_\beta, Z \in \mathfrak{g}_\gamma$ with $\alpha, \beta, \gamma \in \mathbb{Z}_2$.

In particular, if $\mathfrak{g} = \mathfrak{g}_0 \oplus \mathfrak{g}_1$ is a Lie superalgebra then we have that $\mathfrak{g}_0$ is a Lie algebra and $\mathfrak{g}_1$ has structure of $\mathfrak{g}_0$ -module.

Definition 2.1. Let G be an abelian group. A **commutation factor** β is a map $\beta : G \times G \rightarrow \mathbb{F} \setminus \{0\}$, ($\mathbb{F} = \mathbb{C}$ or $\mathbb{R}$), satisfying the following constraints:

- (1) $\beta(g, h)\beta(h, g) = 1$ for all $g, h \in G$
- (2) $\beta(g, h + k) = \beta(g, h)\beta(g, k)$ for all $g, h, k \in G$
- (3) $\beta(g + h, k) = \beta(g, k)\beta(h, k)$ for all $g, h, k \in G$

The definition above implies, in particular, the following relations:

$$\beta(e, g) = \beta(g, e) = 1, \quad \beta(g, h) = \beta(-h, g), \quad \beta(g, g) = \pm 1 \quad \forall g, h \in G$$

where e denotes the identity element of G . In particular, fixing g one element of G , the induced mapping $\beta_g : G \rightarrow \mathbb{F} \setminus \{0\}$ defines a homomorphism of groups.

Definition 2.2. Let G be an abelian group and β a commutation factor. The (complex or real) G -graded algebra

$$L = \bigoplus_{g \in G} Lg$$

with bracket product $[\cdot, \cdot]$, is called a (G, β) -**color Lie superalgebra** if for any $X \in L_g$, $Y \in L_h$, and $Z \in L$ we have

- (1) $[X, Y] = -\beta(g, h)[Y, X]$ (anticommutative identity)

$$(2) \quad [[X, Y], Z] = [X, [Y, Z]] - \beta(g, h)[Y, [X, Z]] \quad (\text{Jacobi identity})$$

The Jacobi identity above can be rewritten as follows

$$\beta(k, g)[X, [Y, Z]] + \beta(h, k)[Z, [X, Y]] + \beta(g, h)[Y, [Z, X]] = 0$$

for all $X \in L_g$, $Y \in L_h$ and $Z \in L_k$.

Corollary 2.2.1. *Let $L = \bigoplus_{g \in G} L_g$ be a (G, β) -color Lie superalgebra. Then we have*

- (1) L_e is a (complex or real) Lie algebra where e denotes the identity element of G .
- (2) For all $g \in G \setminus \{e\}$, L_g is a representation of L_e . If $X \in L_e$ and $Y \in L_g$, then $[X, Y]$ denotes the action of X on Y .

Examples. (1) For the particular case $G = \{e\}$, $L = L_e$ reduces to a Lie algebra.

(2) If $G = \mathbb{Z}_2 = \{0, 1\}$ and $\beta(1, 1) = -1$ we have *ordinary Lie superalgebras*, i.e. a Lie superalgebra is a $(\mathbb{Z}_2, \beta)$ -color Lie superalgebra where $\beta(i, j) = (-1)^{ij}$ for all $i, j \in \mathbb{Z}_2$.

(3) If $A = \bigoplus_{g \in G} A_g$ is a G -graded associative algebra, then setting

$$[X, Y] = XY - \beta(g, h)YX$$

for $X \in A_g$, $Y \in A_h$, we make A into (G, β) -color Lie superalgebra $[A]_\beta$.

Definition 2.3. A **representation** of a (G, β) -color Lie superalgebra is a mapping $\rho : L \longrightarrow \text{End}(V)$, where $V = \bigoplus_{g \in G} V_g$ is a graded vector space such that

$$[\rho(X), \rho(Y)] = \rho(X)\rho(Y) - \beta(g, h)\rho(Y)\rho(X)$$

for all $X \in L_g$, $Y \in L_h$

As for all $g, h \in G$ we have $\rho(L_g)V_h \subseteq V_{g+h}$, then any V_g has the structure of a L_e -module. In particular if we consider the adjoint representation ad_L we have that every L_g has structure of L_e -module.

Let $L = \bigoplus_{g \in G} L_g$ be a (G, β) -color Lie superalgebra. The **descending central sequence** of L [13] is defined by

$$\mathcal{C}^0(L) = L, \quad \mathcal{C}^{k+1}(L) = [\mathcal{C}^k(L), L] \quad \forall k \geq 0$$

If $\mathcal{C}^k(L) = \{0\}$ for some k , the (G, β) -color Lie superalgebra is called **nilpotent**. The smallest integer k such as $\mathcal{C}^k(L) = \{0\}$ is called the **nilindex** of L .

Also, we are going to define some new **descending sequences of ideals**.

Definition 2.4. [12] Let $L = \bigoplus_{g \in G} L_g$ be a (G, β) -color Lie superalgebra. Then, we define the new descending sequences of ideals $\mathcal{C}^k(L_e)$ (where e denotes the identity element of G) and $\mathcal{C}^k(L_g)$ with $g \in G \setminus \{e\}$, as follows:

$$\mathcal{C}^0(L_e) = L_e, \quad \mathcal{C}^{k+1}(L_e) = [L_e, \mathcal{C}^k(L_e)], \quad k \geq 0$$

and

$$\mathcal{C}^0(L_g) = L_g, \quad \mathcal{C}^{k+1}(L_g) = [L_e, \mathcal{C}^k(L_g)], \quad k \geq 0, \quad g \in G \setminus \{e\}$$

Using the descending sequences of ideals defined above we give an invariant of color Lie superalgebras called **color-nilindex**. We are going to particularize this definition for $G = \mathbb{Z}_2 \times \mathbb{Z}_2$.

Definition 2.5. [13] If $L = L_e \oplus L_a \oplus L_b \oplus L_c$ is a nilpotent $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta)$ -color Lie superalgebra, then L has **color-nilindex** (p_e, p_a, p_b, p_c) , if the following conditions holds:

$$(\mathcal{C}^{p_e-1}(L_e))(\mathcal{C}^{p_a-1}(L_a))(\mathcal{C}^{p_b-1}(L_b))(\mathcal{C}^{p_c-1}(L_c)) \neq 0$$

and

$$\mathcal{C}^{p_e}(\mathbb{L}_e) = \mathcal{C}^{p_a}(\mathbb{L}_a) = \mathcal{C}^{p_b}(\mathbb{L}_b) = \mathcal{C}^{p_c}(\mathbb{L}_c) = 0$$

Definition 2.6. [12] Let $L = \bigoplus_{g \in G} Lg$ be a (G, β) -color Lie superalgebra. L_g is called a **L_e -filiform module** if there exists a decreasing subsequence of vectorial subspaces in its underlying vectorial space V , $V = V_m \supset \dots \supset V_1 \supset V_0$, with dimensions $m, m-1, \dots, 0$, respectively, $m > 0$, and such that $[L_e, V_{i+1}] = V_i$.

Definition 2.7. [12] Let $L = \bigoplus_{g \in G} Lg$ be a (G, β) -color Lie superalgebra. Then L is a **filiform color Lie superalgebra** if the following conditions hold:

- (1) L_e is a filiform Lie algebra where e denotes the identity element of G .
- (2) L_g has structure of L_e -filiform module, for all $g \in G \setminus \{e\}$

For $G = \mathbb{Z}_2 \times \mathbb{Z}_2$ we give another equivalent definition for filiform color Lie superalgebras using the invariant called color-nilindex.

Definition 2.8. [13] Any $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta)$ -color Lie superalgebra $L = L_e \oplus L_a \oplus L_b \oplus L_c$ is a **filiform color Lie superalgebra** if its color-nilindex is exactly

$$(\dim L_e - 1, \dim L_a, \dim L_b, \dim L_c)$$

It is not difficult to see that for $G = \mathbb{Z}_2 \times \mathbb{Z}_2$, there are, up to symmetries, four possible commutation factors β non-degenerated, i.e. $\beta_1, \beta_2, \beta_3$ and β_4 with:

1. $\beta_1(a, a) = \beta_1(b, b) = \beta_1(a, c) = \beta_1(b, c) = -1$
2. $\beta_2(a, a) = \beta_2(b, b) = \beta_2(a, b) = -1$
3. $\beta_3(a, b) = \beta_3(a, c) = \beta_3(b, c) = -1$

in all other cases $\beta_i(-, -) = 1$ with $i \in \{1, 2, 3, 4\}$, thus $\beta_4 \equiv 1$.

Fixing a β_i ($1 \leq i \leq 4$), we will note by $\mathcal{L}^{n,m,p,t}$ the variety of all $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_i)$ -color Lie superalgebras $L = L_e \oplus L_a \oplus L_b \oplus L_c$ with $\dim(L_e) = n+1$, $\dim(L_a) = m$, $\dim(L_b) = p$ and $\dim(L_c) = t$.

Thus, $\mathcal{N}_{q,r,s,u}^{n,m,p,t}$ is the subset of $\mathcal{L}^{n,m,p,t}$ formed by all $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_i)$ -color Lie superalgebras with color-nilindex (t_0, t_1, t_2, t_3) where $t_0 \leq q$, $t_1 \leq r$, $t_2 \leq s$ and $t_3 \leq u$. We observe that the set $\mathcal{N}_{n,m,p,t}^{n,m,p,t}$ is the variety of all nilpotent $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_i)$ -color Lie superalgebras. For simplicity we write $\mathcal{N}^{n,m,p,t}$ instead of $\mathcal{N}_{n,m,p,t}^{n,m,p,t}$.

We denote by $\mathcal{F}^{n,m,p,t}$ the subset of $\mathcal{N}^{n,m,p,t}$ composed of all filiform color Lie superalgebras.

In the particular case of $G = \mathbb{Z}_2 \times \mathbb{Z}_2$ the theorem of adapted basis rests as follows for $L = L_e \oplus \mathbb{L}_a \oplus L_b \oplus L_c \in \mathcal{F}^{n,m,p,t}$:

$$\begin{aligned}
[X_0, X_i] &= X_{i+1}, & 1 \leq i \leq n-1, & \quad [X_0, X_{n-1}] = 0, \\
[X_0, Y_j] &= Y_{j+1}, & 1 \leq j \leq m-1, & \quad [X_0, Y_m] = 0 \\
[X_0, Z_k] &= Z_{k+1}, & 1 \leq k \leq p-1, & \quad [X_0, Z_p] = 0, \\
[X_0, W_s] &= W_{s+1}, & 1 \leq s \leq t-1, & \quad [X_0, W_t] = 0.
\end{aligned}$$

with $\{X_0, X_1, \dots, X_n\}$ a basis of L_e , $\{Y_1, \dots, Y_m\}$ a basis of L_a , $\{Z_1, \dots, Z_p\}$ a basis of L_b and $\{W_1, \dots, W_t\}$ a basis of L_c . The others bracket products are open (they only have to verify the conditions for be a filiform color Lie superalgebra).

The model filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_i)$ -color Lie superalgebra, $L^{n,m,p,t}$, is the simplest filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_i)$ -color Lie superalgebra and it is defined in an adapted basis $\{X_0, X_1, \dots, X_n, Y_1, \dots, Y_m, Z_1, \dots, Z_p, W_1, \dots, W_t\}$ by the following bracket products non-null

$$L^{n,m,p,t} = \begin{cases} [X_0, X_i] = X_{i+1}, & 1 \leq i \leq n-1 \\ [X_0, Y_j] = Y_{j+1}, & 1 \leq j \leq m-1 \\ [X_0, Z_k] = Z_{k+1} & 1 \leq k \leq p-1 \\ [X_0, W_s] = W_{s+1}, & 1 \leq s \leq t-1 \end{cases}$$

We observe that this definition does not depend on the election of the commutation factor β_i .

Note that from now on we will restrict our study to β_1 as commutation factor because this is the most complex commutation factor.

We observe that a *module* $V = V_e \oplus V_a \oplus V_b \oplus V_c$ of the $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra L is a bilinear map of degree e , $L \times V \rightarrow V$ satisfying

$$\forall X \in L_g, Y \in L_h, v \in V : X(Yv) - \beta_i(g, h)Y(Xv) = [X, Y]v$$

color Lie superalgebra cohomology (see e.g. [14]) is defined as follows: in particular, the superspace of q -dimensional cocycles of the $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra $L = L_e \oplus L_a \oplus L_b \oplus L_c$ with coefficients in the L -module $V_e \oplus V_a \oplus V_b \oplus V_c$ will be given, up to symmetry, by

$$C^q(L; V) = \bigoplus_{q_e + q_a + q_b + q_c = q} \text{Hom}(\wedge^{q_e} L_e \otimes S^{q_a} L_a \otimes S^{q_b} L_b \otimes \wedge^{q_c} L_c, V)$$

This space will be graded by $C^q(L; V) = C_e^q(L; V) \oplus C_a^q(L; V) \oplus C_b^q(L; V) \oplus C_c^q(L; V)$ with

$$C_p^q(L; V) = \bigoplus_{\substack{q_e + q_a + q_b + q_c = q \\ q_b + q_c + p_1 \equiv r_1 \pmod{2} \\ q_a + q_c + p_2 \equiv r_2 \pmod{2}}} \text{Hom}(\wedge^{q_e} L_e \otimes S^{q_a} L_a \otimes S^{q_b} L_b \otimes \wedge^{q_c} L_c, V_r)$$

with $p = (p_1, p_2) \in \mathbb{Z}_2 \times \mathbb{Z}_2$ and $r = (r_1, r_2) \in \mathbb{Z}_2 \times \mathbb{Z}_2$.

The *coboundary operator* $\delta^q : C^q(L; V) \rightarrow C^{q+1}(L; V)$, with $\delta^{q+1} \circ \delta^q = 0$ and $q \geq 1$, is defined in general as follows

$$\begin{aligned}
(\delta^q g)(A_0, A_1, \dots, A_q) &= \\
&\sum_{r=0}^q (-1)^r \beta(\gamma + \alpha_0 + \dots + \alpha_{r-1}, \alpha_r) A_r \cdot g(A_0, \dots, \hat{A}_r, \dots, A_q) \\
&+ \sum_{r < s} (-1)^s \beta(\alpha_{r+1} + \dots + \alpha_{s-1}, \alpha_s) g(A_0, \dots, A_{r-1}, [A_r, A_s], A_{r+1}, \dots, \hat{A}_s, \dots, A_q),
\end{aligned}$$

with $g \in C^q(L; V)$ of degree γ , and $A_0, A_1, \dots, A_q \in L$ are homogeneous with degrees $\alpha_0, \alpha_1, \dots, \alpha_q$ respectively.

Let $Z^q(L; V)$ be the kernel of δ^q and let $B^q(L; V)$ be the image of δ^{q-1} , thus we have that $B^q(L; V) \subset Z^q(L; V)$. The elements of $Z^q(L; V)$ are the q -cocycles, the elements of $B^q(L; V)$ are the q -coboundaries. Thus, we have the cohomology groups

$$H^q(L; V) = Z^q(L; V) / B^q(L; V)$$

$$H_p^q(L; V) = Z_p^q(L; V) / B_p^q(L; V), \text{ if } G = \mathbb{Z}_2 \times \mathbb{Z}_2 \text{ then } p = e, a, b, c$$

We will consider in our study the 2-cocycles of degree e , $Z_e^2(L^{n,m,p,t}; L^{n,m,p,t})$ with $L^{n,m,p,t}$ the model filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra. Taking into account the law of $L^{n,m,p,t}$ the condition that have to verify $\psi \in C_e^2(L^{n,m,p,t}; L^{n,m,p,t})$ to be a 2-cocycle rests

$$\begin{aligned}
(\delta^2 \psi)(A_0, A_1, A_2) &= [A_0, \psi(A_1, A_2)] - \beta_1(\alpha_0, \alpha_1)[A_1, \psi(A_0, A_2)] + \\
&\beta_1(\alpha_0 + \alpha_1, \alpha_2)[A_2, \psi(A_0, A_1)] - \psi([A_0, A_1], A_2) \\
&+ \beta_1(\alpha_1, \alpha_2)\psi([A_0, A_2], A_1) + \psi(A_0, [A_1, A_2]) = 0
\end{aligned}$$

for all $A_0, A_1, A_2 \in L^{n,m,p,t}$. We note that $L^{n,m,p,t}$ has the structure of a $L^{n,m,p,t}$ -module via the adjoint representation.

On the other hand, recall that an *infinitesimal deformation* φ of the $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra L , $L = L_e \oplus L_a \oplus L_b \oplus L_c$, it is a bilinear map $\varphi : L \times L \longrightarrow L$ that satisfies the following two relations (for more details in general see [12]):

- (1) $\varphi(X, Y) = -\beta_1(g, h)\varphi(Y, X)$, for all $X \in L_g$ and $Y \in L_h$.
- (2) $\mu \circ \varphi + \varphi \circ \mu = 0$, with μ representing the law of L , i.e. for all $X \in L_g$, $Y \in L_h$ and $Z \in L_k$ we have

$$\begin{aligned}
(\mu \circ \varphi + \varphi \circ \mu)(X, Y, Z) &= \\
&\beta_1(k, g)\mu(X, \varphi(Y, Z)) + \beta_1(h, k)\mu(Z, \varphi(X, Y)) + \beta_1(g, h)\mu(Y, \varphi(Z, X)) + \\
&\beta_1(k, g)\varphi(X, \mu(Y, Z)) + \beta_1(h, k)\varphi(Z, \mu(X, Y)) + \beta_1(g, h)\varphi(Y, \mu(Z, X)) = 0
\end{aligned}$$

For an arbitrary group grading G and an admissible commutation factor β we have the following result

Theorem 2.8.1. [12] (1) Any filiform (G, β) -color Lie superalgebra law μ is isomorphic to $\mu_0 + \varphi$ where μ_0 is the law of the model filiform (G, β) -color Lie superalgebra and φ is an infinitesimal deformation of μ_0 verifying that $\varphi(X_0, X) = 0$ for all $X \in L$, with X_0 the characteristic vector of model one.

(2) Conversely, if φ is an infinitesimal deformation of a model filiform (G, β) -color Lie superalgebra law μ_0 with $\varphi(X_0, X) = 0$ for all $X \in L$, then the law $\mu_0 + \varphi$ is a filiform (G, β) -color Lie superalgebra law iff $\varphi \circ \varphi = 0$.

$\varphi \circ \varphi(X, Y, Z) = \beta(k, g)\varphi(X, \varphi(Y, Z)) + \beta(h, k)\varphi(Z, \varphi(X, Y)) + \beta(g, h)\varphi(Y, \varphi(Z, X))$ for all $X \in L_g, Y \in L_h$ and $Z \in L_k$.

So, any filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra is a linear deformation of the model filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra. We observe too that, in particular the most interesting deformations are the infinitesimal deformations φ that verify $\varphi \circ \varphi = 0$ (in the sense of Jacobi), i.e. the infinitesimal deformations that are *linearly integrable*.

Next, we present the correspondence between 2-cocycles and infinitesimal deformations.

Proposition 2.9. [13] ψ is an infinitesimal deformation of $L^{n,m,p,t}$ iff ψ is a 2-cocycle of degree e , $\psi \in Z_e^2(L^{n,m,p,t}; L^{n,m,p,t})$.

So, in order to determine all the filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebras it is only necessary to compute the infinitesimal deformations or so called 2-cocycles of degree e , that vanish on the characteristic vector X_0 .

Lemma 2.10. [13] Let $Z^2(L; L)$ be the 2-cocycles $Z_e^2(L^{n,m,p,t}; L^{n,m,p,t})$ that vanish on the characteristic vector X_0 with $L^{n,m,p,t} = L = L_e \oplus L_a \oplus L_b \oplus L_c$. Then, $Z^2(L; L)$ can be divided into ten subspaces, i.e.

1. If $\beta_i = \beta_1$, then

$$\begin{aligned} Z^2(L; L) &= Z^2(L; L) \cap \text{Hom}(L_e \wedge L_e, L_e) \oplus Z^2(L; L) \cap \text{Hom}(L_e \wedge L_a, L_a) \oplus \\ &\quad Z^2(L; L) \cap \text{Hom}(L_e \wedge L_b, L_b) \oplus Z^2(L; L) \cap \text{Hom}(L_e \wedge L_c, L_c) \oplus \\ &\quad Z^2(L; L) \cap \text{Hom}(S^2 L_a, L_e) \oplus Z^2(L; L) \cap \text{Hom}(S^2 L_b, L_e) \oplus \\ &\quad Z^2(L; L) \cap \text{Hom}(L_c \wedge L_c, L_e) \oplus Z^2(L; L) \cap \text{Hom}(L_a \wedge L_b, L_c) \oplus \\ &\quad Z^2(L; L) \cap \text{Hom}(L_a \otimes L_c, L_b) \oplus Z^2(L; L) \cap \text{Hom}(L_b \otimes L_c, L_a) \\ &= H_1 \oplus H_2 \oplus H_3 \oplus H_4 \oplus H_5 \oplus H_6 \oplus H_7 \oplus H_8 \oplus H_9 \oplus H_{10} \end{aligned}$$

3. DIMENSION OF $Z^2(L; L)$ WITH β_1 AS COMMUTATION FACTOR

As $Z^2(L; L) = H_1 \oplus H_2 \oplus H_3 \oplus H_4 \oplus H_5 \oplus H_6 \oplus H_7 \oplus H_8 \oplus H_9 \oplus H_{10}$ then it will be enough calculate the dimensions of such subspaces.

We can decompose $\varphi \in Z^2(L; L)$ as $\varphi = h_1 + h_2 + h_3 + h_4 + h_5 + h_6 + h_7 + h_8 + h_9 + h_{10}$ with $h_i \in H_i$. Thus, the condition that $h_1 \in \text{Hom}(L_e \wedge L_e, L_e)$ has to verify to be a cocycle is exactly (for more details see [13])

$$(1) [X_i, h_1(X_j, X_k)] - [X_j, h_1(X_i, X_k)] + [X_k, h_1(X_i, X_j)] - h_1([X_i, X_j], X_k) + h_1([X_i, X_k], X_j) + h_1(X_i, [X_j, X_k]) = 0$$

and also $X_0 \notin \text{Im } h_1$ (analogously $X_0 \notin \text{Im } h_5, X_0 \notin \text{Im } h_6$ and $X_0 \notin \text{Im } h_7$).

But taking into account the expression of L , the above equation can be simplified to

$$(1) [X_0, h_1(X_j, X_k)] - h_1(X_{j+1}, X_k) - h_1(X_j, X_{k+1}) = 0$$

Similarly, we obtain the following final equations for the remaining $h_i \in H_i$:

- (2) $[X_0, h_2(X_j, Y_k)] - h_2(X_{j+1}, Y_k) - h_2(X_j, Y_{k+1}) = 0$
- (3) $[X_0, h_3(X_j, Z_k)] - h_3(X_{j+1}, Z_k) - h_3(X_j, Z_{k+1}) = 0$
- (4) $[X_0, h_4(X_j, W_k)] - h_4(X_{j+1}, W_k) - h_4(X_j, W_{k+1}) = 0$
- (5) $[X_0, h_5(Y_j, Y_k)] - h_5(Y_{j+1}, Y_k) - h_5(Y_j, Y_{k+1}) = 0$
- (6) $[X_0, h_6(Z_j, Z_k)] - h_6(Z_{j+1}, Z_k) - h_6(Z_j, Z_{k+1}) = 0$
- (7) $[X_0, h_7(W_j, W_k)] - h_7(W_{j+1}, W_k) - h_7(W_j, W_{k+1}) = 0$
- (8) $[X_0, h_8(Y_j, Z_k)] - h_8(Y_{j+1}, Z_k) - h_8(Y_j, Z_{k+1}) = 0$
- (9) $[X_0, h_9(Y_j, W_k)] - h_9(Y_{j+1}, W_k) - h_9(Y_j, W_{k+1}) = 0$
- (10) $[X_0, h_{10}(Z_j, W_k)] - h_{10}(Z_{j+1}, W_k) - h_{10}(Z_j, W_{k+1}) = 0$

In order to obtain the dimension of each subspace of cocycles H_i we will apply the $\mathfrak{sl}(2, \mathbb{C})$ -**module Method** [1]. Next we will start studying $H_1 = Z^2(L; L) \cap \text{Hom}(L_e \wedge L_e, L_e)$.

Recall the basics properties of the Lie algebra $\mathfrak{sl}(2, \mathbb{C})$ and its finite-dimensional modules, see e.g. [2], [9]:

$\mathfrak{sl}(2, \mathbb{C}) = \langle X_-, H, X_+ \rangle$ with the commutation relations that follow:

$$\begin{cases} [X_+, X_-] = H \\ [H, X_+] = 2X_+, \\ [H, X_-] = -2X_-. \end{cases}$$

If we consider $V = \langle e_1, \dots, e_n \rangle$ as a n -dimensional $\mathfrak{sl}(2, \mathbb{C})$ -module, then there will be a unique structure of an irreducible $\mathfrak{sl}(2, \mathbb{C})$ -module in V [2]:

$$\begin{cases} X_+ \cdot e_i = e_{i+1}, & 1 \leq i \leq n-1, \\ X_+ \cdot e_n = 0, \\ H \cdot e_i = (-n + 2i - 1)e_i, & 1 \leq i \leq n. \end{cases}$$

Note that e_n is the maximal vector of V and its weight (the highest weight of V) is equal to $n-1$.

In general, if we consider $W_0, W_1, \dots, W_k$ $\mathfrak{sl}(2, \mathbb{C})$ -modules, then the space $\text{Hom}(\otimes_{i=1}^k W_i, W_0)$ is too a $\mathfrak{sl}(2, \mathbb{C})$ -module :

$$(\xi \cdot \varphi)(x_1, \dots, x_k) = \xi \cdot \varphi(x_1, \dots, x_k) - \sum_{i=1}^k \varphi(x_1, \dots, \xi \cdot x_i, x_{i+1}, \dots, x_n)$$

with $\xi \in \mathfrak{sl}(2, \mathbb{C})$ and $\varphi \in \text{Hom}(\otimes_{i=1}^k W_i, W_0)$. For our study we will consider $k=2$ and $W_0 = W_1 = W_2 = V_e$, obtaining then

$$(\xi \cdot \varphi)(x_1, x_2) = \xi \cdot \varphi(x_1, x_2) - \varphi(\xi \cdot x_1, x_2) - \varphi(x_1, \xi \cdot x_2).$$

Thus, an element $\varphi \in \text{Hom}(V_e \otimes V_e, V_e)$ is said to be invariant or maximal vector if $X_+ \cdot \varphi = 0$, that is

$$(3.1) \quad X_+ \cdot \varphi(x_1, x_2) - \varphi(X_+ \cdot x_1, x_2) - \varphi(x_1, X_+ \cdot x_2) = 0, \quad \forall x_1, x_2 \in V_e.$$

Next, we are going to consider the structure of irreducible $\mathfrak{sl}(2, \mathbb{C})$ -module in $V_e = \langle X_1, \dots, X_n \rangle = L_e / \mathbb{C}X_0$ obtaining:

$$\begin{cases} X_+ \cdot X_i = X_{i+1}, & 1 \leq i \leq n-1, \\ X_+ \cdot X_n = 0, \end{cases}$$

If we identify the multiplication of X_+ and X_i in the $\mathfrak{sl}(2, \mathbb{C})$ -module $V_e = \langle X_1, \dots, X_n \rangle$ with the bracket $[X_0, X_i]$ in L_e , then the expressions (1) and (3.1) are equivalent. Thus, any skew-symmetric bilinear map $\varphi, \varphi : V_e \wedge V_e \longrightarrow V_e$ will be an element of the space of cocycles H_1 if and only if φ is a maximal vector of the $\mathfrak{sl}(2, \mathbb{C})$ -module $\text{Hom}(V_e \wedge V_e, V_e)$, with $V_e = \langle X_1, \dots, X_n \rangle$. But as each irreducible $\mathfrak{sl}(2, \mathbb{C})$ -module has (up to nonzero scalar multiples) a unique maximal vector, then the dimension of the space of cocycles H_1 is equal to the number of summands of any decomposition of $\text{Hom}(V_e \wedge V_e, V_e)$ into the direct sum of irreducible $\mathfrak{sl}(2, \mathbb{C})$ -modules.

Thanks to the symmetric structure of the weights, instead of to sum the maximal vectors it is possible, and easier, to sum the vectors of weight 0 or 1.

At this point, we are going to apply this $\mathfrak{sl}(2, \mathbb{C})$ -module method for to obtain the dimension of the space of cocycles H_1 .

We will consider a natural basis $\mathcal{B}$ of $\text{Hom}(V_e \wedge V_e, V_e)$:

$$\varphi_{i,j}^s(X_k, X_l) = \begin{cases} X_s & \text{if } (i, j) = (k, l) \\ 0 & \text{in all other cases} \end{cases}$$

where $1 \leq i, j, k, l, s \leq n$, with $i \neq j$ and $\varphi_{i,j}^s = -\varphi_{j,i}^s$. So it is enough to find the basis vectors $\varphi_{i,j}^s$ with weight 0 or 1. The weight of an element $\varphi_{i,j}^s$ is $n + 2(s - i - j) + 1$, that is

$$\begin{aligned} (H \cdot \varphi_{i,j}^s)(X_i, X_j) &= H \cdot \varphi_{i,j}^s(X_i, X_j) - \varphi_{i,j}^s(H \cdot X_i, X_j) - \varphi_{i,j}^s(X_i, H \cdot X_j) \\ &= H \cdot X_s - \varphi_{i,j}^s((-n - 1 + 2i)X_i, X_j) - \varphi_{i,j}^s(X_i, (-n - 1 + 2j)X_j) \\ &= (-n - 1 + 2s)X_s - (-n - 1 + 2i)X_s - (-n - 1 + 2j)X_s \\ &= [n + 2(s - i - j) + 1]X_s \end{aligned}$$

Thus, if n is even we will find the elements $\varphi_{i,j}^s$ with weight 1 and if n is odd we will find those of them with weight 0 (note that if n is even then $\lambda(\varphi)$ is odd, and if n is odd then $\lambda(\varphi)$ is even).

We can consider three times the sequence that corresponds with the weights of $V_e = \langle X_1, X_2, \dots, X_{n-1}, X_n \rangle$ i.e. $-n + 1, -n + 3, \dots, n - 3, n - 1$. Then, we have to count the number of all possibilities to obtain 1 (if n is even) or 0 (if n is odd). Note that $\lambda(\varphi_{i,j}^s) = \lambda(X_s) - \lambda(X_i) - \lambda(X_j)$, where $\lambda(X_s)$ belongs to the last sequence, and $\lambda(X_i), \lambda(X_j)$ belong to the first and second sequences respectively. Taking into account the skew-symmetry of $\varphi_{i,j}^s$, that is $\varphi_{i,j}^s = -\varphi_{j,i}^s$ and $i \neq j$ we obtain the following theorem:

Theorem 1. Let $Z^2(L; L)$ be the 2-cocycles $Z_e^2(L^{n,m,p,t}; L^{n,m,p,t})$ that vanish on the characteristic vector X_0 . Then, if $H_1 = Z^2(L; L) \cap \text{Hom}(L_e \wedge L_e, L_e)$ we have that

$$\dim H_1 = \begin{cases} \frac{n(3n-2)}{8} & \text{if } n \text{ is even} \\ \frac{3n^2-4n+1}{8} + \lfloor \frac{n+1}{4} \rfloor & \text{if } n \text{ is odd} \end{cases}$$

Proof. It can be considered 4 cases where the reasoning is not very difficult, i.e. $n \equiv i \pmod{4}$, with $1 \leq i \leq 3$. $\square$

Similarly, we can apply the above method in order to calculate the dimension of H_2 . Thus, if we consider the structure of $\mathfrak{sl}(2, \mathbb{C})$ -module in $\text{Hom}(V_e \otimes V_a, V_a)$ then we would have that an element $\varphi \in \text{Hom}(V_e \otimes V_a, V_a)$ is said to be invariant or maximal vector if $X_+ \cdot \varphi = 0$, that is

$$(3.2) \quad X_+ \cdot \varphi(x_1, x_2) - \varphi(X_+ \cdot x_1, x_2) - \varphi(x_1, X_+ \cdot x_2) = 0, \quad \forall x_1 \in V_e, \forall x_2 \in V_a.$$

In this case we are going to consider the structure of irreducible $\mathfrak{sl}(2, \mathbb{C})$ -module in $V_e = \langle X_1, \dots, X_n \rangle = L_e / \mathbb{C}X_0$ and in $V_a = \langle Y_1, \dots, Y_n \rangle = L_a$, thus in particular:

$$\begin{cases} X_+ \cdot X_i = X_{i+1}, & 1 \leq i \leq n-1 \\ X_+ \cdot X_n = 0 \\ X_+ \cdot Y_j = Y_{j+1}, & 1 \leq j \leq m-1 \\ X_+ \cdot Y_m = 0 \end{cases}$$

We identify the multiplication of X_+ and X_i in the $\mathfrak{sl}(2, \mathbb{C})$ -module $V_e = \langle X_1, \dots, X_n \rangle$, with the bracket product $[X_0, X_i]$ in L_e . Analogously with $X_+ \cdot Y_j$ and $[X_0, Y_j]$. Thanks to these identifications, the expression to be a cocycle of H_2 :

$$(2) \quad [X_0, h_2(X_j, Y_k)] - h_2(X_{j+1}, Y_k) - h_2(X_j, Y_{k+1}) = 0$$

and 3.2 are equivalent, so any skew-symmetric bilinear map $\varphi, \varphi : V_e \wedge V_a \longrightarrow V_a$ will be an element of H_2 if and only if φ is a maximal vector of the $\mathfrak{sl}(2, \mathbb{C})$ -module $\text{Hom}(V_e \wedge V_a, V_a)$, with $V_e = \langle X_1, \dots, X_n \rangle$ and $V_a = L_a$. But, as each $\mathfrak{sl}(2, \mathbb{C})$ -module has (up to nonzero scalar multiples) a unique maximal vector, then the dimension of H_2 is equal to the number of summands of any decomposition of $\text{Hom}(V_e \wedge V_a, V_a)$ into direct sum of irreducible $\mathfrak{sl}(2, \mathbb{C})$ -modules.

As each irreducible module contains either a unique (up to scalar multiples) vector of weight 0 or a unique vector of weight 1, then we will sum them.

Next, we consider a natural basis of $\text{Hom}(V_e \wedge V_a, V_a)$ consisting of the following maps where $1 \leq s, j, l \leq m$ and $1 \leq i, k \leq n$:

$$\varphi_{i,j}^s(X_k, Y_l) = \begin{cases} Y_s & \text{if } (i, j) = (k, l) \\ 0 & \text{in all other cases} \end{cases}$$

It will be enough to find the basis vectors $\varphi_{i,j}^s$ with weight 0 or 1. It is not difficult to see that the weight of an element $\varphi_{i,j}^s$ (with respect to H) is

$$\lambda(\varphi_{i,j}^s) = \lambda(Y_s) - \lambda(X_i) - \lambda(Y_j) = n + 2(s - i - j) + 1.$$

Thus, if n is even then $\lambda(\varphi)$ is odd, and if n is odd then $\lambda(\varphi)$ is even. So, if n is even it will be sufficient to find the elements $\varphi_{i,j}^s$ with weight 1 and if n is

odd it will be sufficient to find those with weight 0. To do that we consider the three sequences that correspond with the weights of $V_e = \langle X_1, \dots, X_n \rangle$, $V_a = \langle Y_1, Y_2, \dots, Y_m \rangle$ and $V_a = \langle Y_1, Y_2, \dots, Y_m \rangle$, i.e.: $-n+1, -n+3, \dots, n-3, n-1$; $-m+1, -m+3, \dots, m-3, m-1$ and $-m+1, -m+3, \dots, m-3, m-1$.

We shall have to count the number of all possibilities to obtain 1 (if n is even) or 0 (if n is odd). Note that $\lambda(\varphi_{i,j}^s) = \lambda(Y_s) - \lambda(X_i) - \lambda(Y_j)$, where $\lambda(Y_s)$ belongs to the last sequence, and $\lambda(X_i)$, $\lambda(Y_j)$ belong to the first and second sequences respectively. Thus, we obtain the following theorem.

Theorem 2. Let $Z^2(L; L)$ be the 2-cocycles $Z_e^2(L^{n,m,p,t}; L^{n,m,p,t})$ that vanish on the characteristic vector X_0 . Then, if $H_2 = Z^2(L; L) \cap \text{Hom}(L_e \wedge L_a, L_a)$ we have

$$\dim H_2 = \begin{cases} \frac{4nm - n^2 + 1}{4} & \text{if } n \text{ is odd, } n < 2m + 1 \\ \frac{4nm - n^2}{4} & \text{if } n \text{ is even, } n < 2m + 1 \\ m^2 & \text{if } n \geq 2m + 1 \end{cases}$$

Proof. It can be considered 4 cases where the reasoning is not very difficult, i.e. $n \equiv i \pmod{4}$, with $1 \leq i \leq 3$. $\square$

Similarly to the previous reasoning we can obtain the equivalent result for H_3 and H_4 (see the dimensions in the Main Theorem 1).

Next, we are going to apply the $\mathfrak{sl}(2, \mathbb{C})$ -module method in order to compute the dimension of $H_5 = Z^2(L; L) \cap \text{Hom}(S^2 L_a, L_e)$.

Thus, we consider the structure of $\mathfrak{sl}(2, \mathbb{C})$ -module in $\text{Hom}(V_a \otimes V_a, V_e)$ and then we have that an element $\varphi \in \text{Hom}(V_a \otimes V_a, V_e)$ is said to be invariant or maximal vector if $X_+ \cdot \varphi = 0$, that is

$$(3.3) \quad X_+ \cdot \varphi(x_1, x_2) - \varphi(X_+ \cdot x_1, x_2) - \varphi(x_1, X_+ \cdot x_2) = 0, \quad \forall x_1, x_2 \in V_a.$$

On the other hand, a cocycle φ belongs to H_5 it will be a symmetric bilinear map $\varphi, \varphi : S^2 L_a \rightarrow L_e$, such that

$$(5) \quad [X_0, h_5(Y_j, Y_k)] - h_5(Y_{j+1}, Y_k) - h_5(Y_j, Y_{k+1}) = 0$$

Then, we consider the structure of an irreducible $\mathfrak{sl}(2, \mathbb{C})$ -module in $V_e = \langle X_1, \dots, X_n \rangle = L_e / \mathbb{C}X_0$ and in $V_a = \langle Y_1, \dots, Y_m \rangle = L_a$, thus in particular:

$$\begin{cases} X_+ \cdot X_i = X_{i+1}, & 1 \leq i \leq n-1 \\ X_+ \cdot X_n = 0 \\ X_+ \cdot Y_j = Y_{j+1}, & 1 \leq j \leq m-1 \\ X_+ \cdot Y_m = 0 \end{cases}$$

We identify the multiplication of X_+ and X_i in the $\mathfrak{sl}(2, \mathbb{C})$ -module $V_e = \langle X_1, \dots, X_n \rangle$, with the bracket product $[X_0, X_i]$ in L_e . Analogously with $X_+ \cdot Y_j$ and $[X_0, Y_j]$. Thanks to these identifications the equation (5) to be a cocycle of H_5 and the equation 3.3 are equivalent, so any symmetric bilinear map $\varphi, \varphi : S^2 V_a \rightarrow V_e$ will be an element of H_5 if and only if φ is a maximal vector

of the $\mathfrak{sl}(2, \mathbb{C})$ -module $\text{Hom}(S^2 V_a, V_e)$, with $V_e = \langle X_1, \dots, X_n \rangle$ and $V_a = L_a$. But as each $\mathfrak{sl}(2, \mathbb{C})$ -module has (up to nonzero scalar multiples) a unique maximal vector, then the dimension of H_5 is equal to the number of summands of any decomposition of $\text{Hom}(S^2 V_a, V_e)$ into direct sum of irreducible $\mathfrak{sl}(2, \mathbb{C})$ -modules.

As each irreducible module contains either a unique (up to scalar multiples) vector of weight 0 or a unique vector of weight 1, then we will sum them.

Next, we consider a natural basis of $\text{Hom}(S^2 V_a, V_e)$ consisting of the following maps where $1 \leq s \leq n$ and $1 \leq i, j, k, l \leq m$:

$$\varphi_{i,j}^s(Y_k, Y_l) = \begin{cases} X_s & \text{if } (i, j) = (k, l) \\ 0 & \text{in all other cases} \end{cases}$$

It will be enough to find the basis vectors $\varphi_{i,j}^s$ with weight 0 or 1. It is not difficult to see that the weight of an element $\varphi_{i,j}^s$ is

$$\lambda(\varphi_{i,j}^s) = \lambda(X_s) - \lambda(Y_i) - \lambda(Y_j) = 2m - n + 2(s - i - j) + 1.$$

Remark 3.1. If n is even then $\lambda(\varphi)$ is odd, and if n is odd then $\lambda(\varphi)$ is even. So, if n is even it will be sufficient to find the elements $\varphi_{i,j}^s$ with weight 1 and if n is odd it will be sufficient to find those of them with weight 0.

In order to find the elements with weight 0 or 1, we can consider the three sequences that correspond with the weights of $V_a = \langle Y_1, Y_2, \dots, Y_{m-1}, Y_m \rangle$, $V_a = \langle Y_1, Y_2, \dots, Y_{m-1}, Y_m \rangle$ and $V_e = \langle X_1, X_2, \dots, X_{n-1}, X_n \rangle$, i.e.: $-m+1, -m+3, \dots, m-3, m-1$; $-m+1, -m+3, \dots, m-3, m-1$ and $-n+1, -n+3, \dots, n-3, n-1$.

We shall have to count the number of all possibilities to obtain 1 (if n is even) or 0 (if n is odd). Note that $\lambda(\varphi_{i,j}^s) = \lambda(X_s) - \lambda(Y_i) - \lambda(Y_j)$, where $\lambda(X_s)$ belongs to the last sequence, and $\lambda(Y_i)$, $\lambda(Y_j)$ belong to the first and second sequences respectively. Taking into account the symmetry of $\varphi_{i,j}^s$ we obtain the following theorem:

Theorem 5. *If $H_5 = Z^2(L; L) \cap \text{Hom}(S^2 L_a, L_e)$, then we have the following values for the dimension of H_5*

$$\dim H_5 = \begin{cases} \frac{m(m+1)}{2} & \text{if } n \geq 2m-1 \\ \frac{1}{8}(4mn - n^2 + 2n + 3) & \text{if } n < 2m-1, \quad n \equiv 1 \pmod{4} \text{ and } m \text{ odd, or} \\ & n \equiv 3 \pmod{4} \text{ and } m \text{ even} \\ \frac{1}{8}(4mn - n^2 + 2n - 1) & \text{if } n < 2m-1, \quad n \equiv 3 \pmod{4} \text{ and } m \text{ odd, or} \\ & n \equiv 1 \pmod{4} \text{ and } m \text{ even} \\ \frac{1}{8}(4mn - n^2 + 2n) & \text{if } n < 2m-1 \quad \text{and } n \text{ even} \end{cases}$$

Proof. It is convenient to distinguish the following six cases where the reasoning for each case is not hard:

- (1). $n \geq 2m - 1$
- (2). $n \leq 2m - 1$, n even.
- (3). $n \leq 2m - 1$, $n \equiv 1 \pmod{4}$, m odd.
- (4). $n \leq 2m - 1$, $n \equiv 3 \pmod{4}$, m even.
- (5). $n \leq 2m - 1$, $n \equiv 1 \pmod{4}$, m even.
- (6). $n \leq 2m - 1$, $n \equiv 3 \pmod{4}$, m odd.

□

Similarly to the previous reasoning we can obtain the equivalent result for H_6 , H_7 , H_8 , H_9 and H_{19} (see the dimensions in the Main Theorem 1).

Main Theorem 1. *Let $L^{n,m,p,t} = L$ be the model filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra. Let $Z^2(L; L)$ be the 2-cocycles $Z_e^2(L; L)$ that vanish on the characteristic vector X_0 . Then, $\dim(Z^2(L; L)) = \sum_{i=1}^{10} \dim H_i$ with*

$$\begin{aligned}
 \dim H_1 &= \begin{cases} \frac{n(3n-2)}{8} & \text{if } n \text{ is even} \\ \frac{3n^2-4n+1}{8} + \lfloor \frac{n+1}{4} \rfloor & \text{if } n \text{ is odd} \end{cases} \\
 \dim H_2 &= \begin{cases} \frac{4nm-n^2+1}{4} & \text{if } n \text{ is odd, } n < 2m+1 \\ \frac{4nm-n^2}{4} & \text{if } n \text{ is even, } n < 2m+1 \\ m^2 & \text{if } n \geq 2m+1 \end{cases} \\
 \dim H_3 &= \begin{cases} \frac{4np-n^2+1}{4} & \text{if } n \text{ is odd, } n < 2p+1 \\ \frac{4np-n^2}{4} & \text{if } n \text{ is even, } n < 2p+1 \\ p^2 & \text{if } n \geq 2p+1 \end{cases} \\
 \dim H_4 &= \begin{cases} \frac{4nt-n^2+1}{4} & \text{if } n \text{ is odd, } n < 2t+1 \\ \frac{4nt-n^2}{4} & \text{if } n \text{ is even, } n < 2t+1 \\ t^2 & \text{if } n \geq 2t+1 \end{cases}
 \end{aligned}$$

$$\begin{aligned}
\dim H_5 &= \begin{cases} \frac{m(m+1)}{2} & \text{if } n \geq 2m-1 \\ \frac{1}{8}(4mn - n^2 + 2n + 3) & \text{if } n < 2m-1, \quad n \equiv 1(\text{mod } 4) \text{ and } m \text{ odd, or} \\ & n \equiv 3(\text{mod } 4) \text{ and } m \text{ even} \\ \frac{1}{8}(4mn - n^2 + 2n - 1) & \text{if } n < 2m-1, \quad n \equiv 3(\text{mod } 4) \text{ and } m \text{ odd, or} \\ & n \equiv 1(\text{mod } 4) \text{ and } m \text{ even} \\ \frac{1}{8}(4mn - n^2 + 2n) & \text{if } n < 2m-1 \quad \text{and } n \text{ even} \end{cases} \\
\dim H_6 &= \begin{cases} \frac{p(p+1)}{2} & \text{if } n \geq 2p-1 \\ \frac{1}{8}(4pn - n^2 + 2n + 3) & \text{if } n < 2p-1, \quad n \equiv 1(\text{mod } 4) \text{ and } p \text{ odd, or} \\ & n \equiv 3(\text{mod } 4) \text{ and } p \text{ even} \\ \frac{1}{8}(4pn - n^2 + 2n - 1) & \text{if } n < 2p-1, \quad n \equiv 3(\text{mod } 4) \text{ and } p \text{ odd, or} \\ & n \equiv 1(\text{mod } 4) \text{ and } p \text{ even} \\ \frac{1}{8}(4pn - n^2 + 2n) & \text{if } n < 2p-1 \quad \text{and } n \text{ even} \end{cases} \\
\dim H_7 &= \begin{cases} \frac{t(t-1)}{2} & \text{if } n \geq 2t-1 \\ \frac{1}{8}(4tn - n^2 - 2n - 1) & \text{if } n < 2t-1, \quad n \equiv 1(\text{mod } 4) \text{ and } t \text{ odd, or} \\ & n \equiv 3(\text{mod } 4) \text{ and } t \text{ even} \\ \frac{1}{8}(4tn - n^2 - 2n + 3) & \text{if } n < 2t-1, \quad n \equiv 3(\text{mod } 4) \text{ and } t \text{ odd, or} \\ & n \equiv 1(\text{mod } 4) \text{ and } t \text{ even} \\ \frac{1}{8}(4tn - n^2 - 2n) & \text{if } n < 2t-1 \quad \text{and } n \text{ even} \end{cases}
\end{aligned}$$

(1). If $m + p - t$ is even

$$\dim H_8 = \begin{cases} mt & \text{if } p \geq m+t \\ tp-1 & \text{if } p < m+t, p = m-t+2 \\ tp & \text{if } p < m+t, p < m-t+2 \\ \frac{1}{4}(-m^2 - t^2 - p^2 + 2tp + 2mt + 2mp) & \text{if } p < m+t, p > m-t+2, \\ & p \geq t-m+2 \\ mp & \text{if } p < m+t, p > m-t+2, \\ & p < t-m+2 \end{cases}$$

(2). If $m+p-t$ is odd

$$\dim H_8 = \begin{cases} mt & \text{if } p \geq m+t-1 \\ tp & \text{if } p < m+t-1, p \leq m-t+1 \\ \frac{1}{4}(-m^2 - t^2 - p^2 + 2tp + 2mt + 2mp + 1) & \text{if } p < m+t-1, p > m-t+1, \\ & p \geq t-m+1 \\ mp & \text{if } p < m+t-1, p > m-t+1, \\ & p < t-m+1 \end{cases}$$

(1). If $m+t-p$ is even

$$\dim H_9 = \begin{cases} mp & \text{if } t \geq m+p \\ tp-1 & \text{if } t < m+p, t = m-p+2 \\ tp & \text{if } t < m+p, t < m-p+2 \\ \frac{1}{4}(-m^2 - t^2 - p^2 + 2tp + 2mt + 2mp) & \text{if } t < m+p, t > m-p+2, \\ & t \geq p-m+2 \\ mt & \text{if } t < m+p, t > m-p+2, \\ & t < p-m+2 \end{cases}$$

(2). If $m+t-p$ is odd

$$\dim H_9 = \begin{cases} mp & \text{if } t \geq m + p - 1 \\ tp & \text{if } t < m + p - 1, t \leq m - p + 1 \\ \frac{1}{4}(-m^2 - t^2 - p^2 + 2tp + 2mt + 2mp + 1) & \text{if } t < m + p - 1, t > m - p + 1, \\ & t \geq p - m + 1 \\ mt & \text{if } t < m + p - 1, t > m - p + 1, \\ & t < p - m + 1 \end{cases}$$

(1). If $t + p - m$ is even

$$\dim H_{10} = \begin{cases} mt & \text{if } p \geq m + t \\ mp - 1 & \text{if } p < m + t, p = t - m + 2 \\ mp & \text{if } p < m + t, p < t - m + 2 \\ \frac{1}{4}(-m^2 - t^2 - p^2 + 2tp + 2mt + 2mp) & \text{if } p < m + t, p > t - m + 2, \\ & p \geq m - t + 2 \\ tp & \text{if } p < m + t, p > t - m + 2, \\ & p < m - t + 2 \end{cases}$$

(2). If $t + p - m$ is odd

$$\dim H_{10} = \begin{cases} mt & \text{if } p \geq m + t - 1 \\ mp & \text{if } p < m + t - 1, p \leq t - m + 1 \\ \frac{1}{4}(-m^2 - t^2 - p^2 + 2tp + 2mt + 2mp + 1) & \text{if } p < m + t - 1, p > t - m + 1, \\ & p \geq m - t + 1 \\ tp & \text{if } p < m + t - 1, p > t - m + 1, \\ & p < m - t + 1 \end{cases}$$

4. COMPUTING A BASIS OF $Z^2(L; L) \cap \text{Hom}(S^2 L_a, L_e)$

In this section we are going to develop a method that permit us to compute a basis of $H_5 = Z^2(L; L) \cap \text{Hom}(S^2 L_a, L_e)$ in each case, and with β_1 as commutation factor. We will consider the subspace H_5 because of it is completely composed by linearly integrable cocycles (it is not difficult to see that $h_5 \circ h_5 = 0$). Thus, if we have $h_5 \in H_5$ and $L^{n,m,p,t}$ is the model filiform color Lie superalgebra, then $L^{n,m,p,t} + h_5$ will be too a filiform color Lie superalgebra.

Recall the weight of an element $\varphi_{i,j}^s, \varphi_{i,j}^s \in \text{Hom}(S^2 V_a, V_e)$, defined by

$$\varphi_{i,j}^s(Y_k, Y_l) = \begin{cases} X_s & \text{if } (i, j) = (k, l) \\ 0 & \text{in all other cases} \end{cases}$$

with $1 \leq s \leq n$ and $1 \leq i, j, k, l \leq m$. Then the weight $\lambda(\varphi_{i,j}^s)$ is

$$\lambda(\varphi_{i,j}^s) = \lambda(X_s) - \lambda(Y_i) - \lambda(Y_j) = 2m - n + 2(s - i - j) + 1.$$

We are going to introduce a simpler weight, it corresponds to the action of the diagonalizable derivation d , $d \in \text{Der} L^{n,m,p,t}$, defined by:

$$d(X_0) = X_0, \quad d(X_i) = iX_i, \quad d(Y_j) = jY_j, \quad d(Z_k) = kZ_k, \quad d(W_s) = sW_s;$$

with $1 \leq i \leq n, 1 \leq j \leq m, 1 \leq k \leq p, 1 \leq s \leq t$.

This weight will be denoted by $p(\varphi)$. We have that

$$p(\varphi_{i,j}^s) = s - i - j.$$

We have the following relationships between the two weights:

$$\begin{aligned} \lambda(\varphi) &= 2p(\varphi) + 2m - n + 1, \\ p(\varphi) &= \frac{1}{2}(\lambda(\varphi) - 2m + n - 1). \end{aligned}$$

Let φ be an element of H_5 , with weight $\lambda(\varphi)$. As φ is a maximal vector of the $\mathfrak{sl}(2, \mathbb{C})$ -module $\text{Hom}(S^2V_a, V_e)$, its weight $\lambda(\varphi)$ is always a nonnegative integer, $\lambda(\varphi) \geq 0$.

On the other hand, $p(\varphi)$ is always less or equal than $n - 2$, $p(\varphi) \leq n - 2$. In fact, $\varphi_{1,1}^n$ is an element with maximal weight $p(\varphi)$, $p(\varphi_{1,1}^n) = n - 2$. So, we have the following estimates for $p(\varphi)$:

$$(4.1) \quad \frac{n - 2m - 1}{2} \leq p(\varphi) \leq n - 2.$$

In order to get a basis of H_5 it is enough to obtain the basis for each subspace $H_5(p)$ of H_5 , spanned by all the elements with weight p such that p satisfies (4.1). Let $\psi_{k,s}$ be an element of $\text{Hom}(S^2V_a, V_e)$ with weight p , $p(\psi_{k,s}) = s - 2k$, and defined by

$$\psi_{k,s}(Y_i, Y_i) = \begin{cases} X_s & \text{if } i = k \\ 0 & \text{in the other case} \end{cases}$$

with $1 \leq s \leq n, 1 \leq k \leq m$ and satisfying the equations

$$(4.2) \quad [X_0, \psi_{k,s}(Y_i, Y_j)] - \psi_{k,s}(Y_{i+1}, Y_j) - \psi_{k,s}(Y_i, Y_{j+1}) = 0, \text{ with } 1 \leq i, j \leq m - 1.$$

We observe that $\psi_{k,s}$ is not always a cocycle of H_5 . In particular, $\psi_{k,s}$ will be a cocycle of H_5 if and only if it satisfies the equations

$$[X_0, \psi_{k,s}(Y_i, Y_m)] - \psi_{k,s}(Y_{i+1}, Y_m) = 0, \text{ with } 1 \leq i \leq m.$$

By induction the following formula for $\psi_{k,s}$ can be proved:

$$\psi_{k,s}(Y_i, Y_j) = (-1)^{k-i} \overline{C}_{j-k}^{k-i} X_{i+j+s-2k}$$

with $1 \leq i < j \leq m, k \leq \frac{i+j}{2}$ and to simplify the expressions we have denoted by $\overline{C}_{j-k}^{k-i}$ the expression $C_{j-k}^{k-i} - \frac{1}{2}C_{j-k-1}^{k-i}$. We suppose that $C_t^q = 0$ if $q < 0$ or $t < 0$ or $q > t$, and $C_0^0 = C_t^0 = 1$ with $t > 0$. In the remaining cases we have $C_t^q = \frac{t!}{q!(t-q)!}$.

Proposition 4.1. *The symmetric bilinear map $\psi_{k,s}$ defined by the formula*

$$\psi_{k,s}(Y_i, Y_j) = (-1)^{k-i} \overline{C}_{j-k}^{k-i} X_{i+j+s-2k}, \quad 1 \leq i, j \leq m$$

is a cocycle of H_5 iff

$$p(\psi_{k,s}) = s - 2k \geq n - m - 1.$$

Proof. We only have to check whether $\psi_{k,s}$ satisfies or not the equations

$$[X_0, \psi_{k,s}(Y_i, Y_m)] = \psi_{k,s}(Y_{i+1}, Y_m), \quad \text{with } 1 \leq i \leq m.$$

If $p(\psi_{k,s}) = n - m - 1$, then

$$\psi_{k,s}(Y_1, Y_m) = (-1)^{k-1} \overline{C}_{m-k}^{k-1} X_n$$

and $\psi_{k,s}(Y_2, Y_m) = \dots = \psi_{k,s}(Y_m, Y_m) = 0$ which clearly satisfy the above equations. If $p(\psi_{k,s}) > n - m - 1$, then $\psi_{k,s}(Y_1, Y_m) = \dots = \psi_{k,s}(Y_m, Y_m) = 0$ and also satisfies the cocycle equations of H_5 .

If $p(\psi_{k,s}) < n - m - 1$, then

$$\psi_{k,s}(Y_1, Y_m) = (-1)^{k-1} \overline{C}_{m-k}^{k-1} X_t$$

with $t < n$. If we apply the cocycle equations we have

$$[X_0, \psi_{k,s}(Y_1, Y_m)] = \psi_{k,s}(Y_2, Y_m) = (-1)^{k-2} \overline{C}_{m-k}^{k-2} X_{t+1},$$

but

$$[X_0, \psi_{k,s}(Y_1, Y_m)] = [X_0, (-1)^{k-1} \overline{C}_{m-k}^{k-1} X_t] = (-1)^{k-1} \overline{C}_{m-k}^{k-1} X_{t+1}$$

and then

$$C_{m-k}^{k-2} - \frac{1}{2} C_{m-k-1}^{k-2} = -C_{m-k}^{k-1} + \frac{1}{2} C_{m-k-1}^{k-1},$$

which is a contradiction. $\square$

Proposition 4.2. *Let $\psi \in H_5$ be a cocycle with weight $p = p(\psi) \leq n - m - 2$. Then*

$$\psi = \sum_{s-2k=p} a_k \psi_{k,s}$$

for some numbers a_k .

Proof. Let $\psi \in H_5$ a cocycle with weight p . Then $\psi(Y_i, Y_i) = a_i X_{2i+p}$. We are going to consider the difference $\Psi = \psi - \sum_{s-2k=p} a_k \psi_{k,s}$.

It is easy to check that Ψ is a symmetric bilinear map such that $\Psi(Y_1, Y_1) = \Psi(Y_2, Y_2) = \dots = \Psi(Y_m, Y_m) = 0$.

In fact, as $\psi_{k,s}$ satisfies the equations (4.2) Ψ satisfies them too, which implies that Ψ vanishes. That is, if we fix i with $1 \leq i \leq m-1$, we can prove by induction that $\Psi(Y_i, Y_{i+k}) = 0$, for all $k \geq 0$: We suppose that the relation is true up to k , thanks to (4.2), for $k+1$ we have

$$[X_0, \Psi(Y_i, Y_{i+k})] = 0 = \Psi(Y_{i+1}, Y_{(i+1)+(k-1)}) + \Psi(Y_i, Y_{i+k+1}) = 0 + \Psi(Y_i, Y_{i+k+1})$$

which proves the result. $\square$

Proposition 4.3. *Let ψ be a non-zero cocycle of weight $p = p(\psi) \leq n - m - 2$*

$$\psi = \sum_{s-2k=p} a_k \psi_{k,s}.$$

Then $p \geq n - 2m$.

Proof. Let $\psi = \sum_{s-2k=p} a_k \psi_{k,s}$ be a cocycle with $p < n - 2m$. If ψ is non-zero, then there exists i such that $a_i \neq 0$, and thus $\psi(Y_i, Y_i) = a_i X_{2i+p} \neq 0$. As ψ is a cocycle it can be seen that

$$(adX_0)^{2(m-i)}(\psi(Y_i, Y_i)) = \alpha\psi(Y_m, Y_m)$$

Then $0 \neq a_i X_{m+2p} = \alpha\psi(Y_m, Y_m)$. Thus $\psi(Y_m, Y_m) = a_m X_{m+2p}$ with $a_m \neq 0$ and $m + 2p < n$, so $[X_0, \psi(Y_m, Y_m)] = a_m X_{m+2p+1} \neq 0$ which is a contradiction with the equations that verifies for being a cocycle:

$$[X_0, \psi(Y_m, Y_m)] = \psi([X_0, Y_m], Y_m) + \psi(Y_m, [X_0, Y_m]) = 0.$$

□

Proposition 4.4. *Let ψ be a cocycle of H_5*

$$\psi = \sum_{s-2k=p} a_k \psi_{k,s}$$

with $\max\{\frac{n-2m-1}{2}, n - 2m\} \leq p \leq n - m - 2$. Then ψ is a cocycle iff

$$(adX_0)^{r-1}(\psi(Y_1, Y_m)) = \cdots = (adX_0)(\psi(Y_{r-1}, Y_m)) = \psi(Y_r, Y_m)$$

with $r = n - m - p$.

Proof. As each $\psi_{k,s}$ satisfies the equations (4.2), ψ satisfies them, too. Thus, we have that ψ will be a cocycle of H_5 iff ψ satisfies the equations

$$[X_0, \psi(Y_i, Y_m)] - \psi(Y_{i+1}, Y_m) = 0, \text{ with } 1 \leq i \leq m$$

which proves the result. □

The above proposition give us a method to construct all the cocycles with weight p , $\max\{\frac{n-2m-1}{2}, n - 2m\} \leq p \leq n - m - 2$, and together with Proposition 4.1 the complete description of H_5 can be obtained. An explicit description of H_5 with $n \geq 2m - 1$ will be done in the following section.

5. BASIS OF H_5 FOR $n \geq 2m - 1$

In this section we are going to apply the method described in the above section in order to construct an explicit basis of H_5 . In particular, we shall give a basis of H_5 in the case with more cocycles: $\frac{m(m+1)}{2}$ with $n \geq 2m - 1$ (see Main Theorem 1).

Main Theorem 2. *A basis of the space of cocycles $Z^2(L; L) \cap \text{Hom}(S^2 L_a, L_e)$, with $n \geq 2m - 1$, will be given by the following cocycles*

• *For each p such that $n - m - 1 \leq p \leq n - 2$, there are $\lfloor \frac{n-p}{2} \rfloor$ cocycles of weight p in the basis, that is*

$$\psi_{1,p+2}, \psi_{2,p+4}, \dots, \psi_{\lfloor \frac{n-p}{2} \rfloor, p+2\lfloor \frac{n-p}{2} \rfloor} \quad .$$

- $p = n - 2m$, there is only one cocycle of weight p in the basis, that is

$$\bar{\psi}_{m,n} = a_1 \psi_{1,n-2m+2} + a_2 \psi_{2,n-2m+4} + \cdots + a_{m-1} \psi_{m-1,n-2} + \psi_{m,n}$$

with

$$a_i = 2 + \sum_{q=2}^{m-i} 2^q \left[\prod_{k=1}^{q-1} \sum_{j_k=1}^{m-i-1-\sum_{t=1}^{k-1} j_t} (-1)^{j_k+1} \bar{C}_{m-i-\sum_{t=1}^k j_t}^{j_k} \right], \quad 1 \leq i \leq m-1$$

- For each p such that $n - 2m < p \leq n - m - 2$, there are $l - r + 1 = \lfloor \frac{n-p}{2} \rfloor - (n - m - p) + 1$ cocycles of weight p in the basis, that is

$$\bar{\psi}_{r,p+2r} = a_1 \psi_{1,p+2} + a_2 \psi_{2,p+4} + \cdots + a_{r-1} \psi_{r-1,p+2(r-1)} + \psi_{r,p+2r}$$

and

$$\bar{\psi}_{h,p+2h} = a_1^h \psi_{1,p+2} + a_2^h \psi_{2,p+4} + \cdots + a_{r-1}^h \psi_{r-1,p+2(r-1)} + \psi_{h,p+2h}$$

for $r < h \leq l$, $1 \leq i \leq r-1$, with

$$a_i = 1 + 2(-1)^{r-i+1} \bar{C}_{m-r}^{r-i} + \sum_{q=2}^{r-i} 2^{q-1} \left[\prod_{k=1}^{q-1} \sum_{j_k=1}^{r-i-1-\sum_{t=1}^{k-1} j_t} (-1)^{j_k+1} \bar{C}_{m-i-\sum_{t=1}^k j_t}^{j_k} \right] + \\ + \sum_{q=2}^{r-i} 2^q (-1)^{r-i+q} \left(\prod_{k=1}^{q-1} \sum_{j_k=1}^{r-i-1-\sum_{t=1}^{k-1} j_t} \bar{C}_{m-i-\sum_{t=1}^k j_t}^{j_k} \right) \left(\bar{C}_{m-r}^{r-i-\sum_{t=1}^{q-1} j_t} \right)$$

and

$$a_i^h = 2(-1)^{h-r} \bar{C}_{m-h}^{h-r} + (-1)^{h-r} \bar{C}_{m-h}^{h-r} \sum_{q=2}^{r-i} 2^q \left[\prod_{k=1}^{q-1} \sum_{j_k=1}^{r-i-1-\sum_{t=1}^{k-1} j_t} (-1)^{j_k+1} \bar{C}_{m-i-\sum_{t=1}^k j_t}^{j_k} \right] + \\ 2(-1)^{h-i+1} \bar{C}_{m-h}^{h-i} + \sum_{q=2}^{r-i} 2^q (-1)^{h-i+q} \left(\prod_{k=1}^{q-1} \sum_{j_k=1}^{r-i-1-\sum_{t=1}^{k-1} j_t} \bar{C}_{m-i-\sum_{t=1}^k j_t}^{j_k} \right) \left(\bar{C}_{m-h}^{h-i-\sum_{t=1}^{q-1} j_t} \right)$$

Proof. Thanks to the condition $n \geq 2m - 1$, the weight p can only be contained in the interval $-1 \leq p \leq n - 2$. As Proposition 4.1 give us the description of the cocycles with $p \geq n - m - 1$, it remains to describe a basis of the cocycles of H_5 such that:

$$n - 2m \leq p \leq n - m - 2.$$

If we fix p satisfying $n - 2m \leq p \leq n - m - 2$, then all the mappings $\psi_{k,s}$ with weight p will be

$$\psi_{1,p+2}, \psi_{2,p+4}, \dots, \psi_{l,p+2l}$$

with $l = \lfloor \frac{n-p}{2} \rfloor$. In fact, as $p \geq n - 2m$, then $l = \lfloor \frac{n-p}{2} \rfloor \leq m$ and $\min(\lfloor \frac{n-p}{2} \rfloor, m) = \lfloor \frac{n-p}{2} \rfloor$. Let ψ be

$$\psi = a_1 \psi_{1,p+2} + a_2 \psi_{2,p+4} + \cdots + a_l \psi_{l,p+2l}.$$

Recall that to simplify the expressions, we denote by $\bar{C}_j^k$ the expression $C_j^k - \frac{1}{2} C_{j-1}^k$.

Proposition 4.4 gives us $r - 1 = n - m - p - 1$ linear equations in $a_1, \dots, a_l$:

$$(adX_0)^i(\psi(Y_{r-i}, Y_m)) = \psi(Y_r, Y_m), \quad 1 \leq i \leq r - 1.$$

That is, if $p > n - 2m$ the resulting system is

$$\begin{aligned} \frac{1}{2}a_1 - a_2\overline{C}_{m-2}^1 + a_3\overline{C}_{m-3}^2 + \dots + a_l(-1)^{l-1}\overline{C}_{m-l}^{l-1} &= \frac{1}{2}a_r + \dots + a_l(-1)^{l-r}\overline{C}_{m-l}^{l-r} \\ \frac{1}{2}a_2 - a_3\overline{C}_{m-3}^1 + \dots + a_l(-1)^{l-2}\overline{C}_{m-l}^{l-2} &= \frac{1}{2}a_r + \dots + a_l(-1)^{l-r}\overline{C}_{m-l}^{l-r} \\ &\vdots \\ \frac{1}{2}a_{r-1} + \dots + a_l(-1)^{l-r+1}\overline{C}_{m-l}^{l-r+1} &= \frac{1}{2}a_r + \dots + a_l(-1)^{l-r}\overline{C}_{m-l}^{l-r}, \end{aligned}$$

and if $p = n - 2m$, then $r = m$, and thus the coefficient of $a_r = a_m$ will be 1 instead of $\frac{1}{2}$. In this case the resulting system in $a_1, \dots, a_{m-1}$ can be expressed by the following matrix

$$\left(\begin{array}{ccccc|c} \frac{1}{2} & -\overline{C}_{m-2}^1 & \overline{C}_{m-3}^2 & \dots & (-1)^{m-2}\overline{C}_1^{m-2} & 1 \\ 0 & \frac{1}{2} & -\overline{C}_{m-3}^1 & \dots & (-1)^{m-3}\overline{C}_1^{m-3} & 1 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & \frac{1}{2} & 1 \end{array} \right)$$

The basis of the set of solutions of this last system can be obtained by induction in the following way $a_{m-1} = 2$; $a_{m-2} = 2 + 2\overline{C}_1^1(a_{m-1})$; $a_{m-3} = 2 + 2\overline{C}_2^1(a_{m-2}) - 2\overline{C}_1^2(a_{m-1})\dots$, that is

$$a_i = 2 + 2 \sum_{j=1}^{m-i-1} (-1)^{j+1} \overline{C}_{m-i-j}^j(a_{i+j}), \quad i = m-1, m-2, \dots, 1.$$

The recursion formula is easy to apply for specific values of m and n . Developing the recursion formula we obtain an explicit expression for a_i :

$$a_i = 2 + \sum_{q=2}^{m-i} 2^q \left[\prod_{k=1}^{q-1} \sum_{j_k=1}^{m-i-1-\sum_{t=1}^{k-1} j_t} (-1)^{j_k+1} \overline{C}_{m-i-\sum_{t=1}^k j_t}^{j_k} \right], \quad 1 \leq i \leq m-1$$

For these values of a_i we obtain the following cocycle that corresponds to the value 1 of the coefficient of $\psi_{m,n}$. Thus, we shall call it $\overline{\psi}_{m,n}$

$$\overline{\psi}_{m,n} = a_1\psi_{1,n-2m+2} + a_2\psi_{2,n-2m+4} + \dots + a_{m-1}\psi_{m-1,n-2} + \psi_{m,n}.$$

In the case $p > n - 2m$ the system admits $l - r + 1 = \lfloor \frac{n-p}{2} \rfloor - n + m + p + 1$ linearly independent solutions that correspond to the following possibilities for the vector $(a_r, a_{r+1}, \dots, a_l)$:

$$(1, 0, \dots, 0), (0, 1, 0, \dots, 0), \dots, (0, \dots, 0, 1)$$

• If $(a_r, a_{r+1}, \dots, a_l) = (1, 0, \dots, 0)$, the resulting system in $a_1, \dots, a_{r-1}$ is given by the matrix

$$\left(\begin{array}{ccccc|c} \frac{1}{2} & -\overline{C}_{m-2}^1 & \overline{C}_{m-3}^2 & \cdots & (-1)^{r-2}\overline{C}_{m-r+1}^{r-2} & \frac{1}{2} + (-1)^r\overline{C}_{m-r}^{r-1} \\ 0 & \frac{1}{2} & -\overline{C}_{m-3}^1 & \cdots & (-1)^{r-3}\overline{C}_{m-r+1}^{r-3} & \frac{1}{2} + (-1)^{r-1}\overline{C}_{m-r}^{r-2} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & \frac{1}{2} & \frac{1}{2} + \overline{C}_{m-r}^1 \end{array} \right)$$

whose solution basis can be obtained by induction in the following way:

$$a_{r-1} = 1 + 2\overline{C}_{m-r}^1; \quad a_{r-2} = 1 - 2\overline{C}_{m-r}^2 + 2\overline{C}_{m-r+1}^1(a_{r-1})\dots, \text{ that is}$$

$$a_i = 1 + 2(-1)^{r-i+1}\overline{C}_{m-r}^{r-i} + 2 \sum_{j=1}^{r-i-1} (-1)^{j+1}\overline{C}_{m-i-j}^j(a_{i+j}), \quad i = r-1, r-2, \dots, 1.$$

Developing the recursion formula we obtain the explicit expression for a_i (enunciated in the Theorem) with $1 \leq i \leq r-1$. Hence for these values of a_i ($1 \leq i \leq r-1$) and $a_r = 1$, $a_{r+1} = \dots = a_l = 0$, we obtain the cocycle $\overline{\psi}_{r,p+2r}$ given by

$$\overline{\psi}_{r,p+2r} = a_1\psi_{1,p+2} + a_2\psi_{2,p+4} + \dots + a_{r-1}\psi_{r-1,p+2(r-1)} + \psi_{r,p+2r}.$$

• In the remaining cases, it can be seen that for each h , $r+1 \leq h \leq l$, such that $a_h = 1$ and $a_k = 0$ with $r \leq k \leq l$ and $k \neq h$, we obtain the cocycle $\overline{\psi}_{h,p+2h}$,

$$\overline{\psi}_{h,p+2h} = a_1^h\psi_{1,p+2} + a_2^h\psi_{2,p+4} + \dots + a_{r-1}^h\psi_{r-1,p+2(r-1)} + \psi_{h,p+2h}$$

for $1 \leq i \leq r-1$, and with a_i^h as in the enunciated of the Theorem.

Thus, for each p all the cocycles described above, and so all the cocycles described in the theorem, are linearly independent. It remains to count them.

In the case $n-m-1 \leq p \leq n-2$ the cocycles obtained are all of the form $\psi_{k,s}$ (see Proposition 4.1). In particular there are $\lfloor \frac{n-p}{2} \rfloor$ cocycles for each p , thus in total for this case we have

$$\sum_{p=n-m-1}^{n-2} \lfloor \frac{n-p}{2} \rfloor = \begin{cases} \frac{m^2+2m}{4} & \text{if } m \text{ is even} \\ \frac{m^2+2m+1}{4} & \text{if } m \text{ is odd} \end{cases}$$

In the case $n-2m \leq p \leq n-m-2$, we have

$$\sum_{p=n-2m}^{n-m-2} \lfloor \frac{n-p}{2} \rfloor - n + m + p + 1 = \begin{cases} \frac{m^2}{4} & \text{if } m \text{ is even} \\ \frac{m^2-1}{4} & \text{if } m \text{ is odd} \end{cases}$$

If we sum, we obtain in total $\frac{m(m+1)}{2}$ cocycles of $Z^2(L; L) \cap \text{Hom}(S^2 L_a, L_e)$ that are linearly independent. As the dimension of the space is $\frac{m(m+1)}{2}$ the proof is finished. $\square$

Corollary. For each ψ of the theorem above, with $n \geq 2m-1$, we will have that

$$L^{n,m,p,t} + \psi$$

is a filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra

6. BASIS OF H_5 FOR $n < 2m - 1$

Now, for $n < 2m - 1$ the construction of a cocycle basis is more complicated. In these cases p can be less than -1 , for example if $p = -2$ there are not $\lfloor \frac{n-p}{2} \rfloor$ mappings $\psi_{k,s}$ with weight p because of $\psi_{1,-2+2}$ does not exist. Thus, in general, for each p the mappings $\psi_{k,s}$ with weight p there will be $\psi_{l,p+2l}$ with $1 \leq p+2l \leq n$, that is

$$\psi_{l,p+2l}, \quad \text{with} \quad \max \left\{ 1, \left\lceil \frac{1-p}{2} \right\rceil \right\} \leq l \leq \left\lfloor \frac{n-p}{2} \right\rfloor$$

So, for $n < 2m - 1$ we have that $\max \left\{ \frac{n-2m-1}{2}, n-2m \right\} = \frac{n-2m-1}{2}$ and thus it can be considered in two cases:

Lemma 6.1. *Let n and m be such that $n < 2m - 1$, and $C = \bigcup_p C_p$, where C_p represents the set of cocycles of weight p . To obtain basis cocycles of C_p we will have firstly to distinguish two cases:*

- **Case 1.** *If p verifies $n - m - 1 \leq p \leq n - 2$. For each one of these p we obtain $\lfloor \frac{n-p}{2} \rfloor - \max \left\{ 1, \left\lceil \frac{1-p}{2} \right\rceil \right\} + 1$ cocycles of weight p in the basis, that is*

$$\psi_{l,p+2l}, \quad \text{with} \quad \max \left\{ 1, \left\lceil \frac{1-p}{2} \right\rceil \right\} \leq l \leq \left\lfloor \frac{n-p}{2} \right\rfloor$$

- **Case 2.** *If p verifies $\left\lceil \frac{n-2m-1}{2} \right\rceil \leq p \leq n - m - 2$. For each one of these p we obtained $\lfloor \frac{n-p}{2} \rfloor - \max \left\{ 1, \left\lceil \frac{1-p}{2} \right\rceil \right\} + 1 - (n - m - 1 - p)$ cocycles of weight p in the basis. $\lfloor \frac{n-p}{2} \rfloor - \max \left\{ 1, \left\lceil \frac{1-p}{2} \right\rceil \right\} + 1$ corresponds to the number of mappings $\psi_{k,s}$ with weight p , and $n - m - 1 - p$ corresponds to the number of equations that a linear combination $\psi = \sum_{s-2k=p} a_k \psi_{k,s}$ has to satisfy to be a cocycle:*

$$(adX_0)^{r-1}(\psi(Y_1, Y_m)) = \dots (adX_0)(\psi(Y_{r-1}, Y_m)) = \psi(Y_r, Y_m)$$

with $r = n - m - p$.

This last case can be subdivided into 4 subcases depending on the possibilities of n and m :

- **Case 2.1** *If n is even. In this case the interval for p is $\frac{n-2m}{2} \leq p \leq n - m - 2$.*
- **Case 2.2** *If $n \equiv 1 \pmod{4}$ and m is even. In this case the interval for p is $\frac{n-2m+1}{2} \leq p \leq n - m - 2$.*
- **Case 2.3** *If $n \equiv 3 \pmod{4}$ and m is odd. The interval for p is $\frac{n-2m+1}{2} \leq p \leq n - m - 2$.*
- **Case 2.4** *If $n \equiv 1 \pmod{4}$ and m is odd. The interval for p is $\frac{n-2m-1}{2} \leq p \leq n - m - 2$.*
- **Case 2.5** *If $n \equiv 3 \pmod{4}$ and m is even. The interval for p is $\frac{n-2m-1}{2} \leq p \leq n - m - 2$.*

Proof. If $n \equiv 1 \pmod{4}$ and m is even, although $\left\lceil \frac{n-2m-1}{2} \right\rceil = \frac{n-2m-1}{2}$ this is not the correct lower bound for p because if $p = \frac{n-2m-1}{2}$ then the number of cocycles with this weight will be 0. In fact, if we put $n = 4k + 1$ and $m = 2k'$ then

$$(k' + k) - (k' - k + 1) + 1 - (n - m - 1 - p) = (4k + 1 - 2k' - 1 - 2(k - k')) = 0$$

So, in this case the interval for p is $\frac{n-2m+1}{2} \leq p \leq n - m - 2$.

If $n \equiv 3 \pmod{4}$ and m is odd, as in the preceding case, $\lceil \frac{n-2m-1}{2} \rceil = \frac{n-2m-1}{2}$ is not the correct lower bound for p because the number of cocycles with this weight is 0. Then, the interval for p is $\frac{n-2m+1}{2} \leq p \leq n - m - 2$. $\square$

Next we are going to particularize for even n . We know that the dimension of the cocycles is $\frac{1}{8}(4mn - n^2 + 2n)$, thus the problem now is how to find such a basis.

Proposition 6.2. *A basis of C_p with $n - m - 1 \leq p \leq n - 2$ for the dimensions*

- $n = 2k$ with $\lceil \frac{m}{2} \rceil \leq k \leq m - 1$ will be given by the following cocycles

$$\psi_{l,p+2l}, \quad \text{with} \quad 1 \leq l \leq \lfloor \frac{n-p}{2} \rfloor$$

- $n = 2k$ with $1 \leq k \leq \lceil \frac{m}{2} \rceil - 1$ will be given by the following cocycles

$$\psi_{l,p+2l}, \quad \text{with} \quad \lceil \frac{1-p}{2} \rceil \leq l \leq \lfloor \frac{n-p}{2} \rfloor$$

Proof. In general (as we have said in Case 1.), for each p such that $n - m - 1 \leq p \leq n - 2$ we obtain $\lfloor \frac{n-p}{2} \rfloor - \max\{1, \lceil \frac{1-p}{2} \rceil\} + 1$ cocycles of weight p in the basis, that is

$$\psi_{l,p+2l}, \quad \text{with} \quad \max\{1, \lceil \frac{1-p}{2} \rceil\} \leq l \leq \lfloor \frac{n-p}{2} \rfloor$$

In our case $n = 2k$ with $\lceil \frac{m}{2} \rceil \leq k \leq m - 1$ we have that

$$\lceil \frac{1-p}{2} \rceil \leq \lceil \frac{1-2k+m+1}{2} \rceil \leq \lceil 1 + \frac{m}{2} - \lceil \frac{m}{2} \rceil \rceil = 1$$

If k is such that $1 \leq k \leq \lceil \frac{m}{2} \rceil - 1$, then as $n - m - 1 \leq p \leq -2$ and $n = 2k$ we have that $2k - m - 1 \leq p \leq -2$. So $\lceil \frac{1-p}{2} \rceil \geq \lceil \frac{1+2}{2} \rceil = 2$ and $\max\{1, \lceil \frac{1-p}{2} \rceil\} = \lceil \frac{1-p}{2} \rceil$ which concludes the proof. $\square$

Proposition 6.3. *A basis of C_p with $-1 \leq p \leq n - 2$ for the dimensions $n = 2k$ with $1 \leq k \leq \lceil \frac{m}{2} \rceil - 1$ will be given by the following cocycles*

$$\psi_{l,p+2l}, \quad \text{with} \quad 1 \leq l \leq \lfloor \frac{n-p}{2} \rfloor$$

Proof. As $-1 \leq p$, then $\lceil \frac{1-p}{2} \rceil \leq 1$. So, $\max\{1, \lceil \frac{1-p}{2} \rceil\} = 1$. $\square$

Proposition 6.4. *The dimension of the space of cocycles $\bigcup_{p=n-m-1}^{n-2} C_p$ with $n = 2k$, $1 \leq k \leq m - 1$, is as follows:*

$$\left\{ \begin{array}{ll} \frac{m^2 + 2m}{4} & \text{if } m \text{ is even and } \lceil \frac{m}{2} \rceil \leq k \leq m-1 \\ \frac{m^2 + 2m + 1}{4} & \text{if } m \text{ is odd and } \lceil \frac{m}{2} \rceil \leq k \leq m-1 \\ \frac{2n + 2nm - n^2}{4} & \text{if } 1 \leq k \leq \lceil \frac{m}{2} \rceil - 1 \end{array} \right.$$

Proof. If $\lceil \frac{m}{2} \rceil \leq k \leq m-1$, there are $\lfloor \frac{n-p}{2} \rfloor$ cocycles for each p , thus in total for this case we have

$$\sum_{p=n-m-1}^{n-2} \lfloor \frac{n-p}{2} \rfloor = \begin{cases} \frac{m^2 + 2m}{4} & \text{if } m \text{ is even} \\ \frac{m^2 + 2m + 1}{4} & \text{if } m \text{ is odd} \end{cases}$$

If $1 \leq k \leq \lceil \frac{m}{2} \rceil - 1$, then we are going to do separately the cases, when m is even and m is odd. When m is even the number of cocycles can be resumed as follows

$$\sum_{p=n-m-1}^{n-2} \lfloor \frac{n-p}{2} \rfloor - 2[1+2+\dots+(\frac{m}{2}-k)] = \frac{m^2 + 2m}{4} - 2[1+2+\dots+\frac{m-n}{2}] = \frac{2mn - n^2 + 2n}{4}$$

And for an odd m we have that

$$\begin{aligned} & \sum_{p=n-m-1}^{n-2} \lfloor \frac{n-p}{2} \rfloor - (\lceil \frac{m}{2} \rceil - k) - 2[1+2+\dots+(\lceil \frac{m}{2} \rceil - k - 1)] = \\ & \frac{m^2 + 2m + 1}{4} - (\frac{m+1-n}{2}) - [(\frac{m-n-1}{2})(\frac{m-n+1}{2})] = \frac{2mn - n^2 + 2n}{4} \end{aligned}$$

□

Theorem 6.4.1. A basis of the space of cocycles $C = \bigcup_p C_p$, with $n = 2m - 2$, will

be given by the following $\frac{1}{8}(4mn - n^2 + 2n)$ cocycles

- For each p such that $n - m - 1 \leq p \leq n - 2$, there are $\lfloor \frac{n-p}{2} \rfloor$ cocycles of weight p in the basis, that is

$$\psi_{1,p+2}, \psi_{2,p+4}, \dots, \psi_{\lfloor \frac{n-p}{2} \rfloor, p+2\lfloor \frac{n-p}{2} \rfloor}.$$

- For each p such that $\frac{n-2m}{2} \leq p \leq n - m - 2$, there are $l - r + 1 = \lfloor \frac{n-p}{2} \rfloor - (n - m - p) + 1$ cocycles of weight p in the basis, that is

$$\overline{\psi}_{r,p+2r} = a_1 \psi_{1,p+2} + a_2 \psi_{2,p+4} + \dots + a_{r-1} \psi_{r-1,p+2(r-1)} + \psi_{r,p+2r}$$

and

$$\overline{\psi}_{h,p+2h} = a_1^h \psi_{1,p+2} + a_2^h \psi_{2,p+4} + \dots + a_{r-1}^h \psi_{r-1,p+2(r-1)} + \psi_{h,p+2h}$$

for $r < h \leq l$, $1 \leq i \leq r - 1$. Here a_i and a_i^h have the same expression as in Main Theorem 2.

Proof. For each p such that $n - m - 1 \leq p \leq n - 2$ the basis cocycles came from Proposition 6.2 with $k = m - 1$. Then, we have to study $\frac{n-2m}{2} \leq p \leq n - m - 2$.

A linear combination $\psi = \sum_{s-2k=p} a_k \psi_{k,s}$ has to satisfy to be a cocycle:

$$(adX_0)^{r-1}(\psi(Y_1, Y_m)) = (adX_0)^{r-2}(\psi(Y_2, Y_m)) = \dots (adX_0)(\psi(Y_{r-1}, Y_m)) = \psi(Y_r, Y_m)$$

with $r = n - m - p$. Thus, the resulting system is

$$\begin{aligned} \frac{1}{2}a_1 - a_2\overline{C}_{m-2}^1 + a_3\overline{C}_{m-3}^2 + \dots + a_l(-1)^{l-1}\overline{C}_{m-l}^{l-1} &= \frac{1}{2}a_r + \dots + a_l(-1)^{l-r}\overline{C}_{m-l}^{l-r} \\ \frac{1}{2}a_2 - a_3\overline{C}_{m-3}^1 + \dots + a_l(-1)^{l-2}\overline{C}_{m-l}^{l-2} &= \frac{1}{2}a_r + \dots + a_l(-1)^{l-r}\overline{C}_{m-l}^{l-r} \\ &\vdots \\ \frac{1}{2}a_{r-1} + \dots + a_l(-1)^{l-r+1}\overline{C}_{m-l}^{l-r+1} &= \frac{1}{2}a_r + \dots + a_l(-1)^{l-r}\overline{C}_{m-l}^{l-r}, \end{aligned}$$

This system is analogous as the system obtained in the proof of Main Theorem 2 (case $p > n - 2m$). Thus, the system admits $l - r + 1 = \lfloor \frac{n-p}{2} \rfloor - n + m + p + 1$ linearly independent solutions that correspond to the following possibilities for the vector $(a_r, a_{r+1}, \dots, a_l)$:

$$(1, 0, \dots, 0), (0, 1, 0, \dots, 0), \dots, (0, \dots, 0, 1)$$

For each p all the cocycles described in the theorem are linearly independent, so all the cocycles of the theorem are linearly independent. It remains to count them.

In the case $n - m - 1 \leq p \leq n - 2$ there are $\lfloor \frac{n-p}{2} \rfloor$ cocycles for each p , thus in total for this case we have

$$\sum_{p=n-m-1}^{n-2} \lfloor \frac{n-p}{2} \rfloor = \begin{cases} \frac{m^2 + 2m}{4} & \text{if } m \text{ is even} \\ \frac{m^2 + 2m + 1}{4} & \text{if } m \text{ is odd} \end{cases}$$

In the case $\frac{n-2m}{2} \leq p \leq n - m - 2$, we have

$$\sum_{p=\frac{n-2m}{2}}^{n-m-2} \lfloor \frac{n-p}{2} \rfloor - n + m + p + 1 = \begin{cases} \frac{m^2 - 4}{4} & \text{if } m \text{ is even} \\ \frac{m^2 - 5}{4} & \text{if } m \text{ is odd} \end{cases}$$

So, we have in total $\frac{2m^2+2m-4}{4}$ which coincides with $\frac{1}{8}(4mn - n^2 + 2n)$ replacing n by $2m - 2$. $\square$

Corollary. For each ψ of the theorem above we will have that

$$L^{2m-2, m, p, t} + \psi$$

is a filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra

If we try to compute a basis of the space of cocycles $Z^2(L; L) \cap \text{Hom}(S^2 L_a, L_e)$, with even n and $n < 2m - 2$ and weight p such that $\frac{n-2m}{2} \leq p \leq n - m - 2$, it is necessary to distinguish two cases: $-1 \leq p \leq n - m - 2$ and $\frac{n-2m}{2} \leq p \leq -2$.

Proposition 6.5. *A basis of C_p with $-1 \leq p \leq n - m - 2$, for the dimensions $n = 2k$, $1 \leq k \leq m - 2$ will be given by the following cocycles where $r = n - m - p$*

$$\bar{\psi}_{r,p+2r} = a_1\psi_{1,p+2} + a_2\psi_{2,p+4} + \cdots + a_{r-1}\psi_{r-1,p+2(r-1)} + \psi_{r,p+2r}$$

and

$$\bar{\psi}_{h,p+2h} = a_1^h\psi_{1,p+2} + a_2^h\psi_{2,p+4} + \cdots + a_{r-1}^h\psi_{r-1,p+2(r-1)} + \psi_{h,p+2h}$$

for $r < h \leq l$, and a_i and a_i^h have the same expression as in Main Theorem 2.

Proof. If $-1 \leq p \leq n - m - 2$, for each p there will be $\lfloor \frac{n-p}{2} \rfloor - (n - m - 1 - p)$ cocycles of weight p in the basis. $\lfloor \frac{n-p}{2} \rfloor$ corresponds to the number of mappings $\psi_{k,s}$ with weight p : $\psi_{l,p+2l}$ with $1 \leq l \leq \lfloor \frac{n-p}{2} \rfloor$. $n - m - 1 - p$ corresponds to the number of equations that a linear combination $\psi = \sum_{s-2k=p} a_k\psi_{k,s}$ has to satisfy to be a cocycle. Thus, the systems that result are similar to ones of the Theorem 6.4.1, case $\frac{n-2m}{2} \leq p \leq n - m - 2$. $\square$

If $\frac{n-2m}{2} \leq p \leq -2$, for each p there will be $\lfloor \frac{n-p}{2} \rfloor - \lceil \frac{1-p}{2} \rceil + 1 - (n - m - 1 - p)$ cocycles of weight p in the basis. $\lfloor \frac{n-p}{2} \rfloor - \lceil \frac{1-p}{2} \rceil + 1$ corresponds to the number of mappings $\psi_{k,s}$ with weight p : $\psi_{l,p+2l}$ with $\lceil \frac{1-p}{2} \rceil \leq l \leq \lfloor \frac{n-p}{2} \rfloor$. $n - m - 1 - p$ corresponds to the number of equations that a linear combination $\psi = \sum_{s-2k=p} a_k\psi_{k,s}$ has to satisfy to be a cocycle:

$$(adX_0)^{r-1}(\psi(Y_1, Y_m)) = \dots (adX_0)(\psi(Y_{r-1}, Y_m)) = \psi(Y_r, Y_m)$$

with $r = n - m - p$. The main problem is that the matrices of the resulting systems are not reduced, so it will be necessary to fix concrete dimensions to solve the problem. Thus, we have the following result

Proposition 6.6. *For the following concrete dimensions a basis of $C = \bigcup_p C_p$ is constituted by:*

- If $n = 2$ and $m = 3$, then we have $\{\psi_{1,1}, \psi_{1,2}, \psi_{2,2}\}$ as a basis of C .
- If $n = 2$ and $m = 4$, then we have $\{\psi_{1,1}, \psi_{1,2}, \psi_{2,1}, \psi_{2,2}\}$ as a basis of C .
- If $n = 4$ and $m = 4$, then we have $\{\psi_{1,1}, \psi_{1,2}, \psi_{1,3}, \psi_{1,4}, \psi_{2,3}, \psi_{2,4}, \bar{\psi}_{2,2}\}$ as a basis of C , with $\bar{\psi}_{2,2} = \psi_{2,2} + 2\psi_{3,4}$.
- If $n = 4$ and $m = 5$, then we have $\{\psi_{1,1}, \psi_{1,2}, \psi_{1,3}, \psi_{1,4}, \psi_{2,2}, \psi_{2,3}, \psi_{2,4}, \psi_{3,4}, \bar{\psi}_{2,1}\}$ as a basis of C , with $\bar{\psi}_{2,1} = \psi_{2,1} + \psi_{3,3}$.
- If $n = 6$ and $m = 5$, then we have $\{\psi_{1,2}, \psi_{1,3}, \psi_{1,4}, \psi_{1,5}, \psi_{1,6}, \psi_{2,4}, \psi_{2,5}, \psi_{2,6}, \psi_{3,6}, \bar{\psi}_{1,1}, \bar{\psi}_{2,3}, \bar{\psi}_{4,6}\}$ as a basis of C , with $\bar{\psi}_{1,1} = \psi_{1,1} - \frac{1}{5}\psi_{3,5}$, $\bar{\psi}_{2,3} = \psi_{2,3} + \psi_{3,5}$, $\bar{\psi}_{4,6} = \frac{2}{3}\psi_{2,2} + \frac{2}{3}\psi_{3,4} + \psi_{4,6}$.
- If $n = 6$ and $m = 6$, then we have $\{\psi_{1,1}, \psi_{1,2}, \psi_{1,3}, \psi_{1,4}, \psi_{1,5}, \psi_{1,6}, \psi_{2,3}, \psi_{2,4}, \psi_{2,5}, \psi_{2,6}, \psi_{3,5}, \psi_{3,6}, \bar{\psi}_{2,2}, \bar{\psi}_{3,4}, \bar{\psi}_{4,5}\}$ as a basis of C , with $\bar{\psi}_{2,2} = \psi_{2,2} - 3\psi_{4,6}$, $\bar{\psi}_{3,4} = \psi_{3,4} + \frac{9}{2}\psi_{4,6}$, $\bar{\psi}_{4,5} = \frac{5}{3}\psi_{2,1} + \frac{4}{3}\psi_{3,3} + \psi_{4,5}$.

- If $n = 8$ and $m = 6$, then we have

$\{\psi_{1,3}, \psi_{1,4}, \psi_{1,5}, \psi_{1,6}, \psi_{1,7}, \psi_{1,8}, \psi_{2,5}, \psi_{2,6}, \psi_{2,7}, \psi_{2,8}, \psi_{3,7}, \psi_{3,8}, \bar{\psi}_{1,2}, \bar{\psi}_{2,4}, \bar{\psi}_{3,5}, \bar{\psi}_{3,6}, \bar{\psi}_{4,7}, \bar{\psi}_{5,8}\}$ as a basis of C , with $\bar{\psi}_{1,2} = \psi_{1,2} + \frac{1}{2}\psi_{4,8}$, $\bar{\psi}_{2,4} = \psi_{2,4} - 3\psi_{4,8}$, $\bar{\psi}_{3,5} = 21\psi_{1,1} + 5\psi_{2,3} + \psi_{3,5}$, $\bar{\psi}_{3,6} = \psi_{3,6} + \frac{9}{2}\psi_{4,8}$, $\bar{\psi}_{4,7} = -28\psi_{1,1} - 5\psi_{2,3} + \psi_{4,7}$, $\bar{\psi}_{5,8} = \frac{5}{4}\psi_{2,2} + \psi_{3,4} + \frac{3}{4}\psi_{4,6} + \psi_{5,8}$.

- If $n = 8$ and $m = 7$, then we have

$\{\psi_{1,2}, \psi_{1,3}, \psi_{1,4}, \psi_{1,5}, \psi_{1,6}, \psi_{1,7}, \psi_{1,8}, \psi_{2,4}, \psi_{2,5}, \psi_{2,6}, \psi_{2,7}, \psi_{2,8}, \psi_{3,6}, \psi_{3,7}, \psi_{3,8}, \psi_{4,8}, \bar{\psi}_{1,1}, \bar{\psi}_{2,3}, \bar{\psi}_{3,5}, \bar{\psi}_{4,6}, \bar{\psi}_{5,7}, \bar{\psi}_{5,8}\}$ as a basis of C , with $\bar{\psi}_{1,1} = \psi_{1,1} + \frac{1}{7}\psi_{4,7}$, $\bar{\psi}_{2,3} = \psi_{2,3} - \psi_{4,7}$, $\bar{\psi}_{3,5} = \psi_{3,5} + 2\psi_{4,7}$, $\bar{\psi}_{4,6} = 3\psi_{2,2} + 2\psi_{3,4} + \psi_{4,6}$, $\bar{\psi}_{5,7} = \frac{7}{2}\psi_{2,1} + \frac{5}{2}\psi_{3,3} + \frac{3}{2}\psi_{4,5} + \psi_{5,7}$, $\bar{\psi}_{5,8} = -\psi_{2,2} - \frac{1}{2}\psi_{3,4} + \psi_{5,8}$.

Proof. We are going to summarize along 6 steps of the procedure to obtain a cocycle basis for the given concrete dimensions n and m ($n < 2m - 1$ and $n = 2k$):

Step 1. If $1 \leq k \leq \lceil \frac{m}{2} \rceil - 1$, then go to Step 2. If not go to step 4.

Step 2. From $p = -1$ to $n - 2$ calculate all the basis cocycles of the form

$$\psi_{l,p+2l}, \quad \text{with} \quad 1 \leq l \leq \lfloor \frac{n-p}{2} \rfloor$$

Go to Step 3.

Step 3. From $p = n - m - 1$ to -2 calculate all the basis cocycles of the form

$$\psi_{l,p+2l}, \quad \text{with} \quad \lceil \frac{1-p}{2} \rceil \leq l \leq \lfloor \frac{n-p}{2} \rfloor$$

Go to Step 5.

Step 4. From $p = n - m - 1$ to $n - 2$ calculate all the basis cocycles of the form

$$\psi_{l,p+2l}, \quad \text{with} \quad 1 \leq l \leq \lfloor \frac{n-p}{2} \rfloor$$

Go to Step 5.

Step 5. From $p = -1$ to $n - m - 2$ calculate all the basis cocycles of the form

$$\bar{\psi}_{r,p+2r} = a_1\psi_{1,p+2} + a_2\psi_{2,p+4} + \cdots + a_{r-1}\psi_{r-1,p+2(r-1)} + \psi_{r,p+2r}$$

where $r = n - m - p$, and

$$\bar{\psi}_{h,p+2h} = a_1^h\psi_{1,p+2} + a_2^h\psi_{2,p+4} + \cdots + a_{r-1}^h\psi_{r-1,p+2(r-1)} + \psi_{h,p+2h}$$

for $r < h \leq l$, and a_i and a_i^h have the same expression as in Main Theorem 2.

Go to Step 6.

Step 6. From $p = \frac{n-2m}{2}$ to -2 calculate all the mappings $\psi_{l,p+2l}$ with $\lceil \frac{1-p}{2} \rceil \leq l \leq \lfloor \frac{n-p}{2} \rfloor$. Put the mappings into a linear combination $\psi = \sum_{s-2k=p} a_k\psi_{k,s}$ and impose that have to verify the equations:

$$(adX_0)^{r-1}(\psi(Y_1, Y_m)) = \cdots (adX_0)(\psi(Y_{r-1}, Y_m)) = \psi(Y_r, Y_m)$$

with $r = n - m - p$. From solving the above equations we obtain a basis of solutions that constitute the basis cocycles that rest.

□

Corollary. For each ψ of the proposition above, with n and m given in each case, we will have that

$$L^{n,m,p,t} + \psi$$

is a filiform $(\mathbb{Z}_2 \times \mathbb{Z}_2, \beta_1)$ -color Lie superalgebra
