Abstract. Let $C_n(q)$ be the number of ideals of codimension n of $\mathbb{F}_q\left[x, y, x^{-1}, y^{-1}\right]$, where $\mathbb{F}_q$ is the finite field with q elements. Kassel and Reutenauer [1] proved that $C_n(q)$ is a polynomial in q for any fixed value of $n \geq 1$. For $q = \frac{3+\sqrt{5}}{2}$, this combinatorial interpretation of $C_n(q)$ is lost. Nevertheless, an unexpected connexion with Fibonacci numbers appears.
Let f_n be the n-th Fibonacci number (following the convention $f_0 = 0$, $f_1 = 1$). Define the series

$$F(t) = \sum_{n\geq 1} f_{2n}\, t^n.$$

We will prove that for each $n \geq 1$,

$$C_n\left(\frac{3+\sqrt{5}}{2}\right) = \lambda_n\, \left(f_{2n}\frac{3+\sqrt{5}}{2} - f_{2n-2}\right),$$

where the integers $\lambda_n \geq 0$ are given by the following generating function

$$\prod_{m\geq 1}\left(1 + F\left(t^m\right)\right) = 1 + \sum_{n\geq 1} \lambda_n\, t^n.$$

Keywords: Fibonacci numbers, ideals, polynomials.

1 Introduction

Let $\mathbb{F}_q$ be the finite field with q elements. We recall that the codimension of the ideal I of the algebra $\mathbb{F}_q\left[x, y, x^{-1}, y^{-1}\right]$ is the dimension of the quotient $\mathbb{F}_q\left[x, y, x^{-1}, y^{-1}\right]/I$ viewed as a vector space over $\mathbb{F}_q$. Kassel and Reutenauer [1] computed the number of ideals of codimention n of $\mathbb{F}_q\left[x, y, x^{-1}, y^{-1}\right]$, denoted $C_n(q)$. The ideals of codimension n of $\mathbb{F}_q[x, y, x^{-1}, y^{-1}]$ are the $\mathbb{F}_q$-points of the Hilbert scheme

$$H^n = Hilb^n\left(\left(\mathbb{A}^1_{\mathbb{F}_q}\backslash\{0\}\right) \times \left(\mathbb{A}^1_{\mathbb{F}_q}\backslash\{0\}\right)\right)$$

of n points of the two-dimensional torus (i.e., of the affine plane minus two distinct straight lines). This scheme is smooth and quasi-projective (see [2]).

The local zeta function of H^n, denoted $Z_{H^n/\mathbb{F}_q}(t)$, is related to $C_n(q)$ by means of the formula

$$C_n(q) = \left. \frac{\frac{d}{dt} Z_{H^n/\mathbb{F}_q}(t)}{Z_{H^n/\mathbb{F}_q}(t)} \right|_{t=0.} \tag{1}$$

Kassel and Reutenauer [2] computed $Z_{H^n/\mathbb{F}_q}(t)$, obtaining that $C_n(q)$ is a self-reciprocal polynomial of degree $2n$, satisfying several number-theoretical properties, e.g.,

$$\begin{aligned} \lim_{q\to 1} \frac{C_n(q)}{(q-1)^2} &= \sum_{d|n} d, \\ C_n(-1) &= \#\left\{(x,y) \in \mathbb{Z}^2 : \quad x^2+y^2 = n\right\}, \\ |C_n(\sqrt{-1})| &= \#\left\{(x,y) \in \mathbb{Z}^2 : \quad x^2+2\,y^2 = n\right\}. \end{aligned}$$

The aim of this paper is to show a rather unexpected relationship between $C_n(q)$ and the Fibonacci numbers. Let f_n be the nth Fibonacci number (following the convention $f_0 = 0$, $f_1 = 1$). Consider the series

$$F(t) = \sum_{n\geq 1} f_{2n}\, t^n \tag{2}$$

and the sequence of integers $\lambda_n \geq 0$ given by

$$\prod_{m\geq 1} \left(1 + F\left(t^m\right)\right) = 1 + \sum_{n\geq 1} \lambda_n\, t^n.$$

We will prove the following result.

Theorem 1. *For each integer $n \geq 1$,*

$$C_n\left(\frac{3+\sqrt{5}}{2}\right) = \lambda_n \left(f_{2n}\frac{3+\sqrt{5}}{2} - f_{2n-2}\right). \tag{3}$$

Furthermore, we will derive a formula for λ_n in terms of the distribution of the divisors of n on short intervals.

2 Proof of the main result

The main ingredient in the proof of Theorem 1 will be the identity

$$\prod_{m\geq 1} \frac{\left(1-t^m\right)^2}{1-\left(q+q^{-1}\right)t^m + t^{2\,m}} = 1 + \sum_{n\geq 1} \frac{C_n(q)}{q^n}, \tag{4}$$

due to Kassel and Reutenauer (see Corollary 1.4 in [1]).

Proof (Proof of Theorem 1). It is well-known that the generating function of f_{2n} is

$$F(t) = \frac{t}{1 - 3\,t + t^2}. \tag{5}$$

Using the identity

$$\frac{(1-t^m)^2}{1-(q+q^{-1})\;t^m + t^{2\,m}} = 1 + \frac{\left(q+q^{-1}-2\right)\;t^m}{1-(q+q^{-1})\;t^m + t^{2\,m}}, \tag{6}$$

computing

$$\left(\frac{3+\sqrt{5}}{2}\right) + \left(\frac{3+\sqrt{5}}{2}\right)^{-1} = 3 \tag{7}$$

and applying (5), we obtain that

$$\prod_{m\geq 1} \frac{(1-t^m)^2}{1-(q+q^{-1})\;t^m + t^{2\,m}}\bigg|_{q=\frac{3+\sqrt{5}}{2}} = \prod_{m\geq 1} \left(1 + F\left(t^m\right)\right). \tag{8}$$

Combining (8) and (4), we conclude that

$$\frac{C_n\left(\frac{3+\sqrt{5}}{2}\right)}{\left(\frac{3+\sqrt{5}}{2}\right)^n} = \lambda_n. \tag{9}$$

Applying the identity $\left(\frac{3+\sqrt{5}}{2}\right)^n = f_{2n}\frac{3+\sqrt{5}}{2} - f_{2n-2}$ to (9) we obtain (3).

3 Applications

Let ℓ_n be the n-th Lucas number, i.e. $\ell_0 = 2$, $\ell_1 = 1$ and $\ell_n = \ell_{n-1} + \ell_{n-2}$. The following result can be used to compute λ_n in terms of the divisors of n.

Corollary 2. *For each $n \geq 1$,*

$$\lambda_n = a_{n,0} + \sum_{k=1}^{n-1} a_{n,k}\,\ell_{2\,k}, \tag{10}$$

where $a_{n,k}$ the number of $d|n$ satisfying

$$\frac{k+\sqrt{k^2+2\,n}}{2} < d \leq k + \sqrt{k^2+2\,n}.$$

Proof. It follows by Theorem 1.2. in [2] that

$$\frac{C_n(q)}{q^n} = \left(q+q^{-1}-2\right)\left(a_{n,0} + \sum_{k=1}^{n-1} a_{n,k}\;\left(q^k + q^{-k}\right)\right). \tag{11}$$

The identity

$$\left(\frac{3+\sqrt{5}}{2}\right)^{k}+\left(\frac{3+\sqrt{5}}{2}\right)^{-k}=\ell_{2\,k}. \tag{12}$$

is well-known. Combining (11), (12), (7) and (9) we obtain (10).
